It sounds like what I think was called a JANZ or something like that tower.
I had ones years ago. Can you send me the pics?

Hi Gary,
They are straight across, about 1.5-2 inches Rolled steel. Very nice welds on them. They are not rohn and I sent a picture to American tower. They said that it was not one of thiers.
Any help would be great. If you look at the pictures you can see the details.
Thanks for the come back

From: W5CPT
Topic: 6075 Message: 6082

I have seen lots of towers similar to the one you have.

Prior to cable & satellite TV many local welding shops jigged up towers of that ilk. It was the only way the farmer could get TV out in the sticks. You will find them all over the Midwest. I seriously doubt if you will find any compatible hardware. However if you load it lightly it should serve you well. Here in West Kentucky you will find A-3s and TA-33s at reasonable heights (30 to 40 feet) on those towers.

Go to this website:

http://www.w4nja.org/n4fz.htm

and you will see a member of our local club with a very similar tower and what it took to get it pointing up.

Check it very closely for damage and rust as this will cause tears to be shed when the antenna that costs 4 times the tower becomes part of the vegetable garden or garage.

One big "Yah-But" - If your installation requires engineering drawings for a permit, you are out of luck. It would cost more than a new Rohn tower to "reverse engineer" drawings for a permit.

Don't skimp on safety, cause saving a buck could cost you your life.

Clint - W5CPT

I agree about the yard sales! Recently I got a circa 1970s CB SWR/Pwr meter
for my QRP rig (Heathkit HW-8) for $3.00. It reads to 100 mws. Can't beat
it!

6084. Re: [ham-antennas] Re: Jpole pics loaded

Yahoo group: ham-antennas (2008)
Date: 2008-09-27 16:35:38 UTC
From: Stan Labinsky Jr.
Topic: 5963 Message: 6084

May I offer another option. A co-linear Jpole which needs no insulator to support the elements at the phasing section. It's totally self supporting.

Instead of it being a pair of half wave elements, 5/8ths wave radiators are used. This allows for a shorter phasing stub, of approximately 13 inches... some might label it an inductor as it is a shorted line of less than a quarter wave's length... your call.

I've seen this antenna mentioned last year on a few sites and the one I built and installed way back in 1894... well 1994 is still up and running despite weather, wind and falling small tree branches. (When you have Silver Maples on the property, you get used to it.)

The whole thing is constructed of 1/2 inch copper pipe and sweat fittings. The only trick is to use the lead free plumbing solder. The stuff trades off the need for a bit more heat for a three x gain in strength. Probably as strong or more than the copper itself. Fourteen years in the wind should be proof of that.

Per the book, this antenna offers a free space gain of a measured and verified 3 dBd, with the main lobe centered on the stub at right angles to the elements versus the specified 2.1dBd of two half wave elements in phase.

I'm attaching the drawing inline to see if it'll make it through the filters. If not, and interest is shown I'll try to add it to the files section here
(something new to try.)

Stan , did you make the upper section and phasing out of ½ pipe??? If so did you brace the phasing section at the main vertical?? I made one from PVC and wire but a stronger one is a good idea.

You will have to post your drawing in the picture section.

Rich , KDØZZ

Stan:

Very good!

If I was to build another one today, I would try using the 5/8 lengths, just to take advantage of the shorter phasing link.

So far my J pole has been great! I have it connected to a scanner in my office and Im hearing railroad traffic nearly 40 miles away!

I am Mister Cheap when it comes to things like this , I made my own with a strip of plastic and a couple of holes for coax and UHF bulk head fittings. I have the ceramic insulators for the 450 ohm line but they are not needed if an acrylic panel is used , you could get by with brass or SS studs, so they are an overkill with mine but add looks. I used a brass bolt as a stud and fed my ground right out the window to a ground rod, works great . I can post a picture if needed.

Norm . I posted a picture of my pass through in the Kd0zz file. It shows the pass through from the outside, you can zoom in on my strain relief on the left. It is just a strip with the coax supported by Adel clamps to the plastic and the supported by a cable. This also has a spring in the cable so there is no stress load going into the plastic. Today it shows three coax runs ,you can see the UFH and the N bulkhead fittings , ground lead and the cluster of wires are for my rotor, my rotor wire got old after 25 years so when I moved I used what was on hand and cheap. I have made a couple of these, working from the junk box is easier then buying from MFJ on the pocket book when you are retired.

Norm,

I am using a 4602 but I bought some additional bulkhead connectors and added another aluminum plate and three more SO-239 connectors and an addition ground lug. It is in a vertical window. I padded the edges of it with foam and then packed a piece of foam in the gap between the two windows and it works just dandy.

6094. Using Alpha Delta DX-SWL for PSK31?

Yahoo group: ham-antennas (2008)
Date: 2008-09-29 01:02:31 UTC
From: va1jgn
Topic: 6094 Message: 6094

I have an Alpha Delta DX-SWL (shortened 40' 1/4 sloper)which I use for SWL. Great antenna for SWL and built to last even in canadian winters. I am purchasing a TS-480SAT for some PSK31 and wondering if I may use this antenna for some low power work. I know that the SWL is not cut for the ham bands so will be getting something up like an DX-EE soon but for now the coax for the SWL is laying on the bench :) so here is my questions

1. Could I use this antenna for some PSK work
2. Would the ATU on the 480SAT be able to tune up 20 or 40 Meters
3. Would I get much RF in the house and rig given the ant setup?

Here is my setup The DX-SWL is attached on the outside corner of the house about 25' up, The downlead is connected to a ground rod but travels very close along the aluminum siding, The antenna feedpoint is only about 10' away from the radio connected with 50' RG58U coax.

Any comments would be appriciated

Good Ideas , on mine I put a narrow strip between the upper and lower window
, stuck it in place with calk that turns clear and put the clear calk around
the pass through. Home Depot also carries a clear □removable□ calk but it is
only good for about 2 years.

From: ash_lee52
Topic: 5969 Message: 6097

Tim

Thanks for all your comments.

I think we have both found that horizontal antennas seem to work better overn poor ground. But I've just put my Hustler 6BTV up with 2 radials per band sort of barely contacting the ground, and its working OK.

As to the Sigma 5... I used to have it mounted in a bucket over a flat metal second roof... and it worked pretty well. Now mounted in a bucket over poor soil it doesn't hear much at all... when I elevate it it works better. I modeled it on EZNEC and that also says it should work better elevated.

But there don 't seem to be many truisms when it comes to antennas.

The MA5V clearly says in the instructions to mount it at least 10 feet off the ground. I believe it is constructed as a off center fed vertical dipole, and if it is lower the "radials" could couple to the ground.

Ash

Let me start over as I think what we have here is my failure to communicate... LOL

You start with a roll of rebar mesh. It is about 50 feet long per roll, and about 6 feet wide.

You roll out another roll, in parallel to the first roll and solder/braze them together. You now have a 12' X 50 foot square of rebar mesh.

You do this with the third, fourth etc. When you are done you have a large curtain of rebar mesh laying on the ground covering your back yard. You will find that a vertical mounted on the ground with this as your ground will work very well, just short of a field of radials in length equal to a radius of 150 feet. It gains this by "looking" like it is a solid sheet of metal covering the yard. RF sees the wire spacing of 6" as nonexistent holes. Just like the grid of a satellite dish.

Prasad,

I used the MFJ 4602 in a horizontal sliding window and it worked just fine.
You could do the same thing with a piece of wood and some bulkhead SO-239
connectors.

Hi all;

I dislike banging an old drum, but here I must.

That window panel, besides being the path your cables follow to get into your shack, is also the path that a lightning strike can... and will follow on its way to the earth.

Now, lightning is fun and impressive to watch... from a distance. The one place you do not want to invite it into is your shack. It must be able to get only as far as the door and no farther. The door here is that entrance panel in your window!

For best effect, the panel should be metallic (can be attached to wood or plastic for support, thermal insulation and attachment to the window frame) and be DIRECTLY connected to your earthing (grounding) system which for best effect on a budget should consist of at least two ground rods set twice their length apart. All the cables that pass through the panel must be electrically connected to it. That includes rotor cables, etc. Rotor cables can by bypassed to the panel with the use of one of the commercially available devices that ICE or PolyPhaser offer. Oh, please do not use old coax cable for your earthing run. That's been proven to be a poorer choice than ordinary copper house wiring. The best choice here is strapping: copper flashing of at least an inch and a half wide, better the three inch stuff. (I don't know if stainless flashing is available, but with the cost of copper, it might be a less expensive alternative. Oddly, the resistance is not as big an issue as is the inductance of the run of your grounding conductor.

The idea is that the bulk of the strike will follow the straightest (really) path to ground, and it best be a an outside one.

Make no mistake about it: even your properly grounded equipment, in a lightning event will actually rise thousands of volts above "ground" potential for an instant and there must be no auxiliary paths the stroke can follow or it will use your radio, etc. as one big fuse. So, even the third wire (the green ones in your power plugs) must also be attached to that panel. You want all of the equipment to jump (in potential) with the stroke, like a prise fighter skipping rope. Or envision all of your equipment as being in a grounded capsule, with only one common entrance and earthing point. Actually, the whole house should be tied to that point: the power line, the phone line and cable, should all be bonded together with a run of copper flashing. You don't want a portion of the stroke to find a better path to earth through you 110 volt wiring and radio equipment.

On another note: lightning arrestors are also part of the mix.
It has been proven that a "near miss" lightning event can put a pulse of energy onto your antenna and into your cables strong enough to damage your receiver's front end. Don't be lulled into a false sense of security by the claims of "DC grounding" in or at the antenna. That only protects the antenna's innards not the stuff attached to it. See the letters "DC"? At the frequency the antenna is designed to operate at, that DC ground is not part of the equation! Read up on metallic insulators (shorted quarter wave stubs) for the "why" of it.
Also, while the practice of disconnecting all the antenna cables during a storm or when

you're away is not a bad idea, the law of averages declares that you WILL be caught off guard once or twice and of course, that's when the stroke will come knocking. People have been struck by lightning from a clear sky... it's been documented, so, a word to the wise...

Again PolyPhaser has literature on the subject.

For some of you this will be particularly difficult, but some is better than nothing if done right. www.PolyPhaser.com can explain it all better than can I, so consider my soapboxing as a sign post pointing toward the way to go and why.

Here's hoping that all the cracks and bangs you hear in the storm are in the distance... the far, far distance!

According to Alpha Delta website you can use it for transmit also.
1. Yes it should work for PSK.
2. It will probably work ok with the tuner in the radio, but according to other factors, feed length, where the antenna is located etc. My suggestion is to try it and see.
3. Again it is where the antenna is located in relationship to the house. Yes you will get RF, but will it effect things in the house is unknown. Again try it and see.

Good luck

I have an Alpha Delta DX-SWL (shortened 40' 1/4 sloper)which I use for SWL. Great antenna for SWL and built to last even in canadian winters. I am purchasing a TS-480SAT for some PSK31 and wondering if I may use this antenna for some low power work. I know that the SWL is not cut for the ham bands so will be getting something up like an DX-EE soon but for now the coax for the SWL is laying on the bench :) so here is my questions

1. Could I use this antenna for some PSK work
2. Would the ATU on the 480SAT be able to tune up 20 or 40 Meters
3. Would I get much RF in the house and rig given the ant setup?

Here is my setup The DX-SWL is attached on the outside corner of the house about 25' up, The downlead is connected to a ground rod but travels very close along the aluminum siding, The antenna feedpoint is only about 10' away from the radio connected with 50' RG58U coax.

Any comments would be appriciated

It shouldn't be to bad unless one, lives near saltwater or similar corrosive location, a simple cleaning once every two years works for me, but it doesn't show on the receiver before or after the junk on the ladder line is worse than the dirt and corrosion on the fittings.

Stan,

PHEW! winded from an obligatory cut & paste of THIS! MANY Thanks!

To abbreviate, the gizmo should have a common point (metal facing) of connection of ALL pieces to a Earth Ground...

Given that unless in use, ALL connections (including the Shack equipment ground) are disconnected on the IN side of the passthru, I am RELATIVELY safe from striked entering??

Where is the best spot to derive the "3rd-wire" AC ground lead for the gear? I haven't heard this one, but it DOES make sense...

And, I DO appreciate the concerns re NEAR strikes... A few months ago, I had a strike on a neighbor's Pine, about 35' from the nearest point on our QTH. Blew out one of MY twisted-pair lines, AND de-sensed my Davis weather station for about 2 hours.

Again, MANY Thanks!

I don□t have any problem. Dissimilar metal can be a problem but any local hardware store/ farm supply will have brass or SS nut and bolts and electrical connectors. The connectors are of a similar type , they are standard electrical connectors so they are made not to react with brass/copper/SS. Just don□t use alum of ferrous metal. I buy mine at a local junk store that buys whatever is on the market, it is called the □electronic exchange□ , many towns have a similar place. It might be a good idea to let each other know what town has what. I was at my son□s house the other day and we went to a store in Colorado Springs called OEM , it has 10times the surplus goodies St. Louis has.

Norm, hi.

There are several sources of "extension boxes" that can be used to tie the third wire ground to your grounding / earthing system. Again, see the PolyPhaser site. But you could probably fabricate one by attaching an outdoor outlet box with a duplex receptacle mounted in it to the entrance panel, with all the correct fittings to make it electrically safe. Then take all the station power from that outlet box.

I'm going to draw fire for saying / suggesting this as the NEC seems to allow for ONLY one grounding point for an electrical service. However that requirement does NOT take into account the multiple paths taken by the strike. I've seen the results of lightning finding its way to ground through the equipment and the wall outlet. Fortunately for my CBing friend, the house didn't catch fire... but his big Palomar sweep tube amp did. Blew the line switch right off the front panel and left a black silhouette of its presence... POOF, it don't work no more! And, oh yes, the branch wiring was toast too.

I've seen it stated that the service entrance grounding connection should be bridged to the station earthing by way of the flashing strap (run OUTSIDE of the building). But still, connecting the station equipment grounding leads (that which feeds all of the station equipment) to the entrance panel will help assure that there will be minimal strike current passing from the coax shell to the chassis safety ground, thereby minimizing potential circuit damage.

The reason that you do not want any of the strike current flowing over the chassis is not intuitively apparent, so here's why.
Consider the chassis path as the primary winding of a transformer and any unshielded signal... or power, or control wiring within the chassis as the secondary. A current pulse flowing through the chassis will induce voltage sufficient to damage the semiconductor junctions of transistors and ICs seemingly safe within the grounded chassis.

Many years ago I had this taught to me by a D.C. company involved in the Tempest program, which has to do with keeping both our sensitive data within and the enemy locked out of our electronics. They discussed what happens when lightning current flows down the grounding cable which runs from the sharp stick on the roof to the rod in the ground. The steeply rising magnetizing field outside will induce a voltage pulse on the interior power and signal wiring which can and will take out computing systems within. Scary stuff... right?

As far as disconnecting your antenna leads, that would work, however, it's the one time it's forgotten that cooks the goose. Better to install lightning arrestors inline with each cable, the good capacitvely coupled guys, not just the old spark gap types.

Cell and commercial sites continue to work right through the worst of electrical storms because a few precautions are followed. The only difference is that these sites are pre-engineered to be lightning/equipment friendly. In many cases we never thought we'd be turning our homes into radio stations so we play catch up with the engineering, but it is not impossible.

BTW, the lightning arrestor has nothing to do with handling the strike potential on the outside of the co-ax - the "grounded" side. It has all to do with the pulse of energy riding on the inside of the cable... the loud "sound" that blows out the ear drum of your radio.

Also, re: near strikes. The RF energy in the near strike could be thought of as the near field of a transmitting antenna. Your antenna, tuned to the frequency of choice will pick up that portion of the energy that it is tuned to and through resonance effects "amplify" it and send it onto the radio's input. That's what an antenna is supposed to do, right? BTW, phone lines and power lines make pretty fair antennas too.

"But, that pulse is on the center conductor and the shield at the same time, a net zero differential, so why's it going to hurt my radio?" Because of the delay of the signal which occurs due to the propagation delay in the cable! The pulse on the outside of the shield will arrive before the pulse on the center conductor, so there WILL be a differential signal at the input, how big it is and how long it lasts will be determined by the antenna, the cable and the strike.

Again PolyPhaser explains it far better than I can. What I know here, I learned from them and having to do it and make it work for a customer... and it does.

Hi !
The DX-SWL series will perform well as a ham band antenna with a wide range outboard tuner. Many hams use them. Your "built-in" tuner will probably tune some bands, not sure. Put a 1:1 balun at the feedpoint or wind about 8 turns of coax into a 8" coil at the feedpoint to make a current choke. Try your tuner, if it doesn't tune use an LDG or MFJ outboard tuner and the results should be good.
Good DX !

Jim

I have a question on the DX-LB.

Based on the premise that a 40 m dipole can be operated on 15 m due to the frequency being 3 x 7 MHz, will the LB work on 60 m since 60 m is 5 x the frequency on 160 meters. (1.8 MHz x 3 = 5.4 MHz)

If the answer is yes, then do the traps (loading coils) interfere or prevent the antenna from working on 60 meters?

Best Regards
Dan Schaaf

Thanks for your comments Kurt

I realize the setup is a lousy transmitting antenna for the ham bands. I will eventualy get something up that is designed for hams since I am becoming interested to join in the hobby rather then just receiving.

I am currently doing a lot of research on antenna principles which I find very interesting but still have a lot more reading. I beleave I understand what the RF pattern coming out of the sloper would look like and if I am correct because my desk in directly behind the feedpoint I would be in a null at that position.

The one qusetion I do not fully understand is the grounded down lead from the antenna. Would this down lead radiate RF also? Since this lead can be easily touched from the ground would it produce an RF burn. Although this down lead is not a bare wire it is resting against the wooden eve of the house, should there be an insulator between the two?

Sorry for the questions but just do not want to catch the house on fire or burn someones hand off :(Any info would be greatly appriciated.

Dan,
We haven't tested it and I haven't heard from a customer who has used it on 60M but I'm sure it will work and probably very well. That would be a lot of wire radiating on 60M so there should be some gain. We do get 15M operation on our antennas from the 40M dipole section. I'll copy this to our resident expert, Don, W8AD, for his comments. Good question !

Subject: Re: [ham-antennas] Using Alpha Delta DX-SWL for PSK31?

Jim

I have a question on the DX-LB.

Based on the premise that a 40 m dipole can be operated on 15 m due to the frequency being 3 x 7 MHz, will the LB work on 60 m since 60 m is 5 x the frequency on 160 meters. (1.8 MHz x 3 = 5.4 MHz)

If the answer is yes, then do the traps (loading coils) interfere or prevent the antenna from working on 60 meters?

Best Regards

Hi !
The DX-SWL series will perform well as a ham band antenna with a wide range outboard tuner. Many hams use them. Your "built-in" tuner will probably tune some bands, not sure. Put a 1:1 balun at the feedpoint or wind about 8 turns of coax into a 8" coil at the feedpoint to make a current choke. Try your tuner, if it doesn't tune use an LDG or MFJ outboard tuner and the results should be good.

Good DX !

Subject: [ham-antennas] Using Alpha Delta DX-SWL for PSK31?

I have an Alpha Delta DX-SWL (shortened 40' 1/4 sloper)which I use for SWL. Great antenna for SWL and built to last even in canadian winters. I am purchasing a TS-480SAT for some PSK31 and wondering if I may use this antenna for some low power work. I know that the SWL is not cut for the ham bands so will be getting something up like an DX-EE soon but for now the coax for the SWL is laying on the bench :) so here is my questions

1. Could I use this antenna for some PSK work
2. Would the ATU on the 480SAT be able to tune up 20 or 40 Meters
3. Would I get much RF in the house and rig given the ant setup?

Here is my setup The DX-SWL is attached on the outside corner of the house about 25' up, The downlead is connected to a ground rod but travels very close along the aluminum siding, The antenna feedpoint is only about 10' away from the radio connected with 50' RG58U coax.

Any comments would be appriciated

Thanks Jim,

I suspect that the theory is OK for a trapless antenna, but I do not know if the LB coils have an effect on thetheory.

Stan I like your J-Pole better than my wire one , I am going to put one together. I do have a question about your print. Ref the 13☐ and 2☐ parts for the phasing section. Are you saying the 2☐ center line is 13☐ from the vertical centerline or to trim the two sections to 13☐. If this was wire like mine no problem with trial and error but cutting and soldering copper pipe I would like to do it once if possible.

Ok thanks Jim for your comments. I do have a choke at the feedpoint so hopefully that will help with any RF on the coax.

Just to get your opinion on the question I directed to Kurt earlier the antenna`s down lead runs very close (1 foot) along the aluminum siding on the house. The top of the down lead is resting on the wooden eve of the house. The bottom of the down lead is attached at the ground to a ground rod.

Would this down lead radiate RF also? Since this lead can be easily touched from the ground would it produce an RF burn. Although this down lead is not a bare wire it is resting against the wooden eve of the house, should there be an insulator between the two?

Sorry to ask these questions but with the down lead so close to the house and siding I am just wondering the dangers if it radiates RF and if I need to use any isolation up on the eve. Any comments would be great.

I think the NEC would go along with a Bonding
Cable (#6 or heaver) between your Shack Ground
and the Power Entrance Box.
As long as all things are Bonded together you should
have No Difference in Potential between the grounds.
Also, Remember that your CATV and you Phone
should also be bonded to the same ground.
Clamps under ground will corrode and should be
welded or brazed ...
Tie your tower base grounds Also into your new
system ground.
I worked in cellular and even with many hits on the
towers the equipment kept working with Good Grounds.

OK, Rich, the dimensions are the cut-to-length values.
If you're concerned with possible problems, and you have the space, like on your deck (you do have a deck, don't you?) you can just slip fit all the pieces together with the antenna laying on its side (but not too close to mother earth) and fire it up with an MFJ analyzer, or even with an H.T. on low power and an SWR bridge.
To check that the pattern is good, you can also lay it flat and walk around it with a field strength meter. Laying it flat appears to cancel the effect of ground reflections when you're checking that the antenna's main lobe is broadside to the co-linear elements (what will be its vertical radiation pattern once it's stood upright).
If you've got any other questions and I'll try to answer them.

From: Don Tyrrell
Topic: 6094 Message: 6122

Hi all,

Interesting comments about the DX-SWL and DX-LB antennas. On the DX-SWL, the down lead circuit, whether it's the ground return through a metal tower or pole, or the down lead wire itself, is part of the antenna circuit. This is true for any quarter wave sloper design. the "antenna wire" portion is "half" the antenna and the return circuit is the other
"half" of the antenna, although it is untuned.

A half wave dipole is two quarter wave sections put together at the feed point. In the same way, a quarter wave ground mounted vertical is "half" of an antenna and the radial/ground system is the other "half". You can look at a quarter wave sloper (which the DX-SWL is) as an upside down vertical where the feed point is up in the air instead of on the ground.

For transmitting, it works best when installed on a tower with an HF size beam on top to be a "capacity hat". The beam is like the radials that were on the ground for a quarter wave vertical, but since the vertical is now turned upside down, the the beam acts like the radials that were on the ground. Just envision the quarter wave sloper as a complete quarter wave ground mounted vertical but it, and its radials, are turned completely upside down.

On a ground mounted vertical, the current lobe at the feed point, which determines its radiation characteristics and efficiency, can be greatly attenuated by surrounding objects like trees, bushes, houses, etc. On the other hand, the quarter wave sloper has its feed point up in the air so it "takes off" with little or no attenuation, assuming it is installed
correctly.

If a quarter wave sloper is installed without a beam on top, it can still work fairly well with
a wide range antenna tuner and several radials (30 ft. or longer) laid out on the ground and connected to the point where the "down lead" circuit comes down to the ground. However, it works best when installed with an HF beam on top, as explained above.

So, there is RF on the down lead and it should be kept away from laying along the house side. A small separation should be OK if running just 100 watts or so. The physics of "Mother Nature" likes complete half wave circuits when it comes to antennas, however they might be made up and/or configured. Remember, you can't fool "Mother Nature" !!!

Now here's a shorter answer on the question about the DX-LB on 60 meters. We simply haven't tested it there (no inquiries) so I don't know what the effects of the coils may or may not be.

Hope my ramblings weren't too long but wanted to make some explanations as much as possible.

Good luck and have fun. Experimentations are part of the fun of the hobby.

Don, W8AD, Alpha Delta Communications, Inc.

Hi Don

<<Now here's a shorter answer on the question about the DX-LB on 60 meters. We simply haven't tested it there (no inquiries) so I don't know what the effects of the coils may or may not be.>>

So, maybe if Alpha Delta ran some tests on 60 meters, they may be able to increase market share if they can demonstrate that it works on 60 m. Even a simple test that shows it can be loaded easily. Obviously, gain and performance are a function of height, flat top vs. invertedV, soil conditions, etc. I am not looking for these specs. Just some factory tests on whether it can be loaded easily, or if it will need a wide range tuner for 60 m.

A half wave dipole is two quarter wave sections put together at the feed point. In the same way, a quarter wave ground mounted vertical is "half" of an antenna and the radial/ground system is the other "half". You can look at a quarter wave sloper (which the DX-SWL is) as an upside down vertical where the feed point is up in the air instead of on the ground.

For transmitting, it works best when installed on a tower with an HF size beam on top to be a "capacity hat". The beam is like the radials that were on the ground for a quarter wave vertical, but since the vertical is now turned upside down, the the beam acts like the radials that were on the ground. Just envision the quarter wave sloper as a complete quarter wave ground mounted vertical but it, and its radials, are turned completely upside down.

On a ground mounted vertical, the current lobe at the feed point, which determines its radiation characteristics and efficiency, can be greatly attenuated by surrounding objects like trees, bushes, houses, etc. On the other hand, the quarter wave sloper has its feed point up in the air so it "takes off" with little or no attenuation, assuming it is

installed
correctly.

If a quarter wave sloper is installed without a beam on top, it can still work fairly well with
a wide range antenna tuner and several radials (30 ft. or longer) laid out on the ground and connected to the point where the "down lead" circuit comes down to the ground. However, it works best when installed with an HF beam on top, as explained above.

So, there is RF on the down lead and it should be kept away from laying along the house side. A small separation should be OK if running just 100 watts or so. The physics of "Mother Nature" likes complete half wave circuits when it comes to antennas, however they might be made up and/or configured. Remember, you can't fool "Mother Nature" !!!

Now here's a shorter answer on the question about the DX-LB on 60 meters. We simply haven't tested it there (no inquiries) so I don't know what the effects of the coils may or may not be.

Hope my ramblings weren't too long but wanted to make some explanations as much as possible.

Good luck and have fun. Experimentations are part of the fun of the hobby.

Don, W8AD, Alpha Delta Communications, Inc.

Hello Ash I'm sorry my PC has been crashed.
Thanks for your helpful information
At your place your BTV work great laid radials on the good couductive soil.I guess.
As to Sigma 5, I don't know what EZNEC means but Sigma or vertical dipole or arrays are developped for DXpeditions , portable operations especially closer to sea side within 1/4 wl.It works great even QRP to unexpected super DX. It does desinged by Force13 from my info.
So the Sigma normally install near the sea and designed up a few feet.
Thans again 73 Tim.

Thanks Don and all who commented on my subject.

Comments are never to long to someone in the learning stage!!

Being informed that the down lead does radiate RF I will get up there and install an insulator where the down lead is touching agaist the wooden eve.

The Down lead does not make any contact with the side of the house but it does run only about 1 foot away so I may give PSK a try on very low power.

I do not have any capacity hat at the top but can easly run a few radials below so thanks for that info. I will be looking at the DX-EE or DX-CC when time permits.

Again Thanks Guys

6126. Re: Feedline passthru window solutions

Yahoo group: ham-antennas (2008)
Date: 2008-10-01 05:15:25 UTC
From: Vee W7IBB
Topic: 6089 Message: 6126

I've enjoyed reading these posts. It got off the inital topic and ended up hitting grounding pretty hard, which is important for us all to understand.

I have a question: I am in a nearly new house. The AC ground was tied to an iron rod buried in the foundation of the house. I assume that there is rot iron running through the foundation and that it is all connected. With all the plumbing being plastic, there is no easy way to tie grounds together. My shack in in the basement about fifty feet away from the place the ground is connected to the rot iron in the foundation. How do I best tie this ground to a ground rod I plan to drive in a window well just outside my shack window? I really don't want to run the ground wire through the house. The ceilings are finished and it will be a real job to do this. Also, I may be creating a fire hazard from a lightning strike. The place where the power enters the home from a buried cable to the meter base is a long ways from this ground. The ground wire goes from the meter base up to the attic and back down to the basement and connects to the iron rod in the foundation. I'm sure this must be in the current NEC code, but I've never seen this type of grounding before.

Any suggestions??
Thanks,

Vee W7IBB Utah

will follow on its way to the earth.
>
> Now, lightning is fun and impressive to watch... from a distance.
The one place you do not want to invite it into is your shack. It
must be able to get only as far as the door and no farther. The door
here is that entrance panel in your window!
>
> For best effect, the panel should be metallic (can be attached to
wood or plastic for support, thermal insulation and attachment to the
window frame) and be DIRECTLY connected to your earthing (grounding)
system which for best effect on a budget should consist of at least
two ground rods set twice their length apart. All the cables that
pass through the panel must be electrically connected to it. That
includes rotor cables, etc. Rotor cables can by bypassed to the
panel with the use of one of the commercially available devices that
ICE or PolyPhaser offer. Oh, please do not use old coax cable for
your earthing run. That's been proven to be a poorer choice than
ordinary copper house wiring. The best choice here is strapping:
copper flashing of at least an inch and a half wide, better the three
inch stuff. (I don't know if stainless flashing is available, but
with the cost of copper, it might be a less expensive alternative.
Oddly, the resistance is not as big an issue as is the inductance of
the run of your grounding conductor.
>
> The idea is that the bulk of the strike will follow the straightest
(really) path to ground, and it best be a an outside one.
>
> Make no mistake about it: even your properly grounded equipment, in
a lightning event will actually rise thousands of volts
above "ground" potential for an instant and there must be no
auxiliary paths the stroke can follow or it will use your radio, etc.

as one big fuse. So, even the third wire (the green ones in your power plugs) must also be attached to that panel. You want all of the equipment to jump (in potential) with the stroke, like a prise fighter skipping rope. Or envision all of your equipment as being in a grounded capsule, with only one common entrance and earthing point. Actually, the whole house should be tied to that point: the power line, the phone line and cable, should all be bonded together with a run of copper flashing. You don't want a portion of the stroke to find a better path to earth through you 110 volt wiring and radio equipment.
>
> On another note: lightning arrestors are also part of the mix.
> It has been proven that a "near miss" lightning event can put a pulse of energy onto your antenna and into your cables strong enough to damage your receiver's front end. Don't be lulled into a false sense of security by the claims of "DC grounding" in or at the antenna. That only protects the antenna's innards not the stuff attached to it. See the letters "DC"? At the frequency the antenna is designed to operate at, that DC ground is not part of the equation! Read up on metallic insulators (shorted quarter wave stubs) for the "why" of it.
> Also, while the practice of disconnecting all the antenna cables during a storm or when you're away is not a bad idea, the law of averages declares that you WILL be caught off guard once or twice and of course, that's when the stroke will come knocking. People have been struck by lightning from a clear sky... it's been documented, so, a word to the wise...
>
> Again PolyPhaser has literature on the subject.

Good morning Vee, I'll take a stab at it...

"I have a question: I am in a nearly new house. The AC ground was tied to an iron rod buried in the foundation of the house.
I assume that there is rot iron running through the foundation and that it is all connected.
With all the plumbing being plastic, there is no easy way to tie grounds together.
My shack in in the basement about fifty feet away from the place the ground is connected to the rot iron in the foundation.
How do I best tie this ground to a ground rod I plan to drive in a window well just outside my shack window?"

First, (correct me if I'm wrong... anybody) the "best" ground should always be the one where your feed lines enter the building since they are the ones which stand the greatest chance of carrying strike current.
That said, I'd take the trouble to double up on the ground rods. Also, I've been warned to check where the foundation footer is poured. In some soils they are apparently quite wide to adequately support the foundation wall. Drive the rod too close to the house and you might just run into it. The argument is that you could damage the footer by trying to pound the rod through it... and besides, by being so close to the building you loose some dissipation effectiveness. Think of a ground plane for an antenna. The antenna should be mounted in the center of it, so same with your ground. The more real estate around the rod, the more area for the stroke energy to be dissipated in.
Also, the old, "two properly spaced apart rods are better than one", applies! It's not just that there's, "a rod out there", but that there's enough there to do the job as it needs to be done.

"I really don't want to run the ground wire through the house.
The ceilings are finished and it will be a real job to do this.
Also, I may be creating a fire hazard from a lightning strike."

The reason you want to bond the power and entrance grounds together is to divert as much of the strike energy away from the house wiring as practicable. Imagine that a strike comes in through the power line and finds your excellent station grounding... through the house wiring that is... it could become painful. (Ya gotta' look at it goin' both ways.)

So, would it be possible to install copper flashing (make it the 3 inch kind) inside the finished room(s) up by the cieling painted to match the wall?
Why three inch? Surface area! Both for the low impedance aspect and for the mass and surface to handle and dissipate safely the heat of the current pulse. Now, running the strap inside the dwelling is NOT the best, but better than having the wiring inside the walls taking the hit.

The other, better, option would be to run the strapping outside! But then you have to find a way to bring it inside to the entrance panel and by your description it sounds like that might not be reasonably done.

However, if you did drive two rods, they could be situated like sentry posts along that run of strapping on the way to the entrance panel from the station ground. That way you do a better job of grounding, and do it more efficiently.

"The place where the power enters the home from a buried cable to the meter base is a long ways from this ground.
The ground wire goes from the meter base up to the attic and back down to the basement and connects to the iron rod in the foundation.
I'm sure this must be in the current NEC code, but I've never seen this type of grounding before."

That your electric service is buried is a good thing as the capacitance of the wiring to the earth will reduce the amplitude of any strike energy coming in that way. Especially the higher frequency stuff.

Question: That ground wire going up to the attic. Is that wire run on the outside of the structure? Going up to the attic and then down the inside of the wall to the iron rod?

If so, and if you do run the strap outside, I'd make the connection to the power company's grounding wire where it leaves the meter base (if I read your description correctly). Even if you ended the run of flashing on the ground below the meter and ran a number six up to the base to make the connection, that would work and not be too obvious. Just make the corner from the strap to the meter base a smooth radius. Lightning absolutely hates sharp bends in its path, they're too inductive.
Or, if you do run it inside, the service entrance end of the strap from your station ground - should be bonded to the service panel.

Just let the iron rod power ground be what it is. It will probably not be too effective at lightning abatement anyway considering the long strange path it's following. But it will save you from accidental electrocution, which is what it's there for.

Another thought comes to mind. That power company ground sounds like a sort of loop, like the primary turn in the transformer I wrote of in a previous post. If so, any other wiring near to it will have a voltage pulse induced into it. May do nothing, or it may pop some home electronics... who knows. But, by your station grounding providing a better path for a lightning stroke, you'll minimise the possibility of that happening.

This statement still says it all!

> I think the NEC would go along with a Bonding
> Cable (#6 or heaver) between your Shack Ground
> and the Power Entrance Box.

>

This may not necessarily be what you might have wanted to hear, but it's how I'd start at it.

Well Norm, the arrestors, if they are the coaxial type can be used as the passthroughs in your entrance panel. Some come with long threaded barrels for just that purpose. By applying them in that way, the shield of the cable will be well connected to the metal plate and then to your grounding system.
If you use the dc blocked devices, they will specify which end connects to what. These do a superior job of protecting the radio's input.

I am no expert , nor do I play one on TV, but I would install a ground rod outside as close to my shack as I could. You can discuss rules an regs until you are blue in the face but direct to ground is good. I have mine that way , it is also with the house ground thru my surge protector. I also have my radio and computer power thru a relay set up and if I lose power in this rural area, the relay drops out and nothing will power up or reboot unless I press the reset button. The main relay is a 4 pole and it supply☐s it☐s own solenoid thru a pole, with a panic button and reset button. This way my satellite internet uplink modem , printers and things are all off line if I am not home and there is a storm.

Fellow Hams:

I have a puzzling problem that I ask help to resolve. I recently PURCHASED a commecially made 20meter dipole. Without boaring everyone with the things that I have done, the Readers Digest version is, with a tuner in-line I can acheive a 1:4 to 1:8 SWR at 14.070 (psk), but without a tuner Its goes up to way over 3:5 - 3:8 swr. I have been told since there is nothing wrong with the antenna itself, and / or the feed line, I am told that its the electric feedline feeding my house , that is causeing the high swr as well as the reason that i am coming through my TV in my house.

Brad,

I am far from an expert having only had my license since May. However I made a 20m dipole and fed it with some cheep RG58U, This caused RF in the shack and this was resolved by replacing the coax with much better screened RG58A/U and a choke at the antenna feed (20 torroids over the coax as discussed here http://www.dx-wire.de/brit/). My RF problems are now sorted.

If you can get an antenna analyser you can check the SWR at the antenna feed and at the end of the feed line and that may be revealing?

rich,
your setup sounds great if there is a power outage to take all of your toys off line before lightning hits. what if you get a lightning strike directly to your ground rod. that will back into your shack, or a lightning strike to your inbound electric supply 30 feet from your house after the line breakers? i know it sounds like a lot of work however when i am not in the shack, everything is disconnected from everything. i have 7 xcievers and three receivers, 4 amps along with a steppir vert. i disconnect from the power source also. takes about 10 minutes, however i dont end up sweating blood if i am 45 minutes from home and we get a sudden thunderstorm.

Y'know, it's always that way! ;-)

As far as running a bonding wire from your station ground to the entrance panel, it could be buried in a slit trench along side, but spaced away from, the foundation... assuming that there's no concrete or blacktop walkways in its path. If done that way, it could also be used to connect the ground rods to the system... kill two birds...
Even if there are paved walks in the way, there are techniques of using water as a drill to enable a wire to be passed under the obstruction.

Y'know, I want to say don't worry about it. Especially if the power company's ground is a really solid one... eight foot rod, heavy connection, no corrosion anywhere, the works.
If the station ground is the path of least impedance to the stroke hitting your antenna, not that much of it will flow through the house wiring... BUT that's a bet I'm not too willing to make. Since what I'm writing here could hang my but on a wall if incorrect... read smoking pile of home after the thunder storm, I have to say that the bonding should be used. Have I seen it not being that big a deal with a really good station ground in place... well, yea, we all can show such examples. But still I've also heard of folks playing Russian Roulette and living to tell about the experience.

The main reason here is that should a stroke of lightning come in through the power lines, and after many years of neglect power company grounds are not to be relied upon, the stroke will use your excellent station ground as its preferred path on the way to earth. D'you want your wiring making up for a deficient electric company ground at the expense of your dwelling? I don't.

Stan

Stan, What is recommended for the 8 wires that go to the rotator.
I've never seen/heard anything on this.
Bill
N0CU

Bill, PolyPhaser offers the IS-RCT exactly for that function. I believe the
I.C.E. engineering does too.

I can vouch for your methodology. On of my local fellow Hams did his usual antenna
disconnecting when a thunderstorm was forecast for the area. He, however, never even thought about disconnecting his ground wire. His Icom 718 was rendered dead and unrepairable(per a call to Icom) when a close lightning strike came in on the ground wire. I put a quick disconnect on my ground wire so I could disconnect everything, but I haven't worked up the courage to reconnect it yet.(G)

Paul , I also unplug the coax on my radios , I don’t have near the set up you do , just one VHF and one HF rig. I keep them disconnected unless I go to use them.

I worry more about my well pump than my radios , my incoming power is a little different , I have a 400amp single phase 240v system , it does not run through a meter but I have 400 amp fuses in a disconnect , then two 200 amp breakers boxes then the standard breakers on each circuit. This is not quite the standard house set up, The disconnect is a 400 amp 3 phase unit with one leg open , I have a 400 amp transformer on the pole in my yard that feeds me alone , the power is measured as current flow from the transformer , if you pull my meter the power is still on.

****
I am concerned about your ground rod running through
the foundation.
A ground rod for AC Power should be away from the
foundation of the house by SIX Feet. If you have it closer
than 6 ft you would only have a half of a ground.
The foundation would shield the other half and would not
be very good. Someone said they were going to drive a
ground rod in a window well. This is almost like no ground
at all.
A number 6 or heaver wire could be buried around your house
and tied into the Service Entrance ground as well as your
phone and CATV.
If you don't tie them together then if you have a shot of
lightning even a half mile away you could have a difference
of potential or voltage of over 1000 Volts. This is what
rips up our radios.
We need to keep everything at the same potential otherwise
it is going to cost us a lot more than the bonding wire.

I just have to add my $.02 worth.

If lightning strikes near by, you might be protected, but if you have a direct strike to your tower, your relay contactor spacing in the off position will mean nothing. You will have several thousand kilovolts within your dwelling. Both from the ground to cloud connection, and also the voltage differential produced because of the I2R losses on whatever you have outside coming inside. A direct lightning discharge can have about 100,000 amps. Consider this, if you have .1 ohms to earth ground in the DC resistance, and you have half of the above current, then you now have a differential potential of 50,000 volts. But wait! you also have an inductance. with the rise time of the strike being probably in the neighborhood of 500,000 volts per uS and if you used 20 feet of #6 wire, you have an inductor in the neighborhood of a couple of uH. This reactance is added in series with the DC resistance. This means that instantaneously, you could develop several more kilovolts inside your home.

When you build your panel, here is what commercial broadcasters do.
1) They put 10' long copper coated ground rods at about 2' from each tower leg.

2) Each coax is bonded to the tower where it leaves the tower to cross the bridge to the antenna.

3) Each coax is bonded to the entrance panel. This is either a brass or copper sheet, 1/4" thick or more. Smaller coax like LMR400/RG8 and smaller sizes will have a "drip loop" of about 36" from the entrance panel to the cable bridge. This increases the inductance, hopefully inducing the strike current to stay at the tower and it's ground. Power for the tower lights go through inductors to keep the EMP power on the tower side, with spark gaps on the tower side to ground.

4) Lightning arrestors are put in the coaxial feed line at the entrance panel to keep the potential within manageable levels inside the coax. There will usually be a difference in potential from the outside of the coax to the center conductor due to propogational delay.

5) Many broadcasters use power isolators on the low voltage 240 or 480 volts AC outside the building to keep EMP outside, and passing the low frequency power to the building. These are either spark gaps or MOV's. The telephone line is also treated. The old style protector was a carbon block, but newer versions also use MOV's.

6) Everything is bonded inside and outside the building with wide copper strap, not wire. The wider the better. I have used up to 6" wide in a broadcast station, and at minimum 3" wide. You can buy it in 50# rolls or by the foot, depending on the vendor. The flatter and straighter you

keep the path, the better. To change directions, cut the strap and solder the splice with a torch making sure the solder flows completely, just like sweating fresh water pipes. Do not use acid core flux. Strap reduces the inductance, carries as much, if not more current and can act like a strip line conductor, like in a UHF transmitter, that promotes the efficient passing of the high frequency components of the lightning currents, voltages and consequently the power of the stroke.

7) Lightning spikes or rods are usually placed at the highest point on the tower. I have seen some that look like a wire kush-ball mounted on the top of the tower. This does 2 things. Attempts to keep the direct strike off the antenna and feed line, and in some instances actually will discharge the leader before it becomes catastrophically dangerous.

Keep in mind also, many broadcasters place their transmitting equipment on rocky mountain tops. So, soil conductivity is low. It is very hard to get a low resistance ground. So the idea is to make the building and it's contents become isolated from the lightning strike. Because of the location, they also are prone to be struck.

Hi Brad,
I can't be sure,but it may be rfi,affecting your swr meter.If you are showing the amount of power output that it should be,but with high swr,thats probably it.About six turns of coax,around a 2 liter soda bottle will make a good rf choke.Or one of the line isolators,from a ham vender,is good and smaller.Try moving the coax,from side to side,and see if the swr changes.If so,your coax is radiating,and needs a choke.Hope this helps.

Steve,

My TV Cacle line coming from the pole is only 2 ft from the dipole, and the power line coming in to the house is about 6 ft away from one leg of the dipole.

HI BRAD.
What are there measurements of your 20m Dipole and have you
used an analyser on it ? have you compared the measurements with a wire
aerial online calculator ? also make sure the 20m dipole when tested is in
clear air nowhere near any overhead wires or buildings.
I have a 20m home brew dipole from my chimney to a pole at the end of the
garden
20m=33foot tip to tip (16.5ft each leg)
is yours fed with coax ???
as if its fed with twin feeder the dipole then becomes a doublet as the feed
line becomes part of the antenna

Whoa! That's a little too close to BOTH for my personal comfort -- can you get more spacing, say 20 feet or more? You want spacing to prevent possible RFI to and from the cable system, but also to keep the power line and the dipole from coming together if either one falls during a windstorm or similar.

Old Phart sounds much better in Spanish. It's "El Viejo Pedoro", and, if you can roll the R in Pedoro, it sounds very impressive. El Vee-eh-ho Pay-doh-rrrroh is as close as I can get, in a phonetic rendering. I used to work with a half Greek, half Mexican CAD drafter, a much younger fellow, and that's what he used to
call me.(G)

OK, That's what I was afraid of. For safety sake, you need to abandon
that location in favor of somewhere farther from the power line.
Remember, power lines KILL!!! so be very careful when removing it.

You would be much better off if you can stay as far from the power line
as possible. Do this even if you have to use a longer coax.

Right on Steve!

From what I've heard and read, if the shack is set up correctly, it can take a direct strike and survive.
Cell sites and commercial sites do that every day... what makes us so different?

Why can an airplane take a strike in the nose to have it exit the tail without harm?
Aircraft fly by wire, there's no mechanical connection between the pilot's cotrols and the control surfaces on the wings. An electronics failure there would be in the news for months after the crash.
BTW, I've recently seen photos of that happening on the Discovery channel or one of the other similar channels on satellite TV with explanation of why it's so. So, why can't we?

If we can keep the image before us of having all of our equipment inside of a capsule who's only connections to the outside world are through that grounded entrance panel, we can.
Sure, the feedline from our dipole may be fried but the equipment will not.

A properly designed transmitter building has a halo of ground cable running around the periphery of the whole structure with multiple ground rods where possible (tops of stony mountains offer poor grounding but are still workable). All of the services come in and out at one point. That way the whole building may jump to several thousands of volts above "ground" during a lightning event but inside no notice of the happening will be taken... the music will still play and the cellular conversations will continue on to divide drivers' attention away form the road around them. If it were not so, the industry would be lobbying Washington to have lightning outlawed.

Expensive, you betcha! But for our own good we can still attempt to approach that goal.

I will now fold up my soapbox and steal off into the night and put on my flameproof jammys.

Goodnight all

Stan

You can put MOV's on those pesky rotor control cables. Use a connector that you like to bring the wires through the entrance panel, but mount the MOV's on the outside.

I have some dual MOV's made by Poly-Phaser that would be great for this. Since I have a bunch, I can make these available to you and the group for $2.00 each plus postage. Count on them costing about $3.00 to ship if you bought 4. They ain't very big. These would protect 2 wires. If you have 8 leads on your cable, then you would only need 4. They have connectors that fit a standard telephone punch down block for tip and ring, and a ring connector for the ground. I can't remember what the firing voltage is, but if anyone is interested, I will go look.

I also have some dual gas discharge types, unknown make, rated for standard telephone lines. These pass the ringer voltage without firing, but clamp at about 130 VAC. Same price, while they last.

I have retired from broadcast station work, and no longer need to keep these in stock.

Also, please remember the 'old' way of just disconnecting your coax from your rig IS NOT a good thing.

A strike, if it should happen to find its way to your coax; will jump to whatever ground you have inside with a fire igniting spark.

Trust me, you dont want a strike looking for a ground in your living room!!

From: Steve Friis
Topic: 6089 Message: 6158

If you don't believe ke4vyn, let me tell you about a guy I knew years ago in El Paso, TX. This guy was a CBer, not a ham, but his lesson is just as good.

He put up a ground plane on the balcony of his appartment using a flag pole to get it just over the top of the roof. Then he had the coax coming into the living room through one of those glass sliding doors. He had removed the coax from the back of the CB because of the storm, and just let it lay on the floor of his apartment.

Well, a thunderstorm did come that day, and he did his routine of pulling the coax off of the radio.

During this storm, a bolt of lightning did indeed hit his antenna, bringing the surge of energy into his apartment. Robert had just left to get his mail and he told me he was on the stair case going down to the courtyard. After he recovered from the huge flash, and very very loud band, he realized he wasn't hurt, so he went back inside the apartment and began to take a survey of the damage. What he saw was so amazing, you had to see it to comprehend the amount of destruction done to his living room, and also the kitchen and even the bedroom. All within less than a couple of milliseconds. Here is what I saw.

The coax was a very stiff blackened fused and melted pile of black copper and insulation. It was stuck to the linoleum. There were signs that the lightning had arced over to the door frame as there was a melted hole in the frame where the coax penetration had been. Along the wall behind the couch, the nails that held the Sheetrock up were blown out, left hanging protruding from their holes. The paint from the floor up to each nail was blistered and pealing. The couch was now sagging badly. This is because the springs inside the cushions were burned and broken. There were burnt circles where the tops of the coiled springs used to be. Under the couch, where an empty beer can laid, the top was removed as if someone had used a cutting torch. The lamp on one of the end tables no longer had a cord. It was burnt off. The bulb was still good though. The TV set was totally gutted, and it was on the other side of the room from the coax and couch. Behind the wall where the TV was is the kitchen. The refrigerator motor was burned out. The AM clock radio he had in the kitchen was burned out. The handles on the kitchen sink showed signs of being burned. On the patio, there was a pile of melted metal, which I am guessing was his flag pole and antenna. All of the wiring in that apartment was damaged, and all of the outlets in all of the rooms in his apartment had to be replaced. They were fused and you couldn't unplug anything that was plugged into them. The only thing not damaged? A lava lamp on the other end table. Why? God only knows.

The down stairs apartment suffered some of the same type of damage, as
the lightning went through the concrete floor to the lower level.

If there had been anyone home, they would have died. It is only because
he left to go down stairs to get his mail that he wasn't electrocuted.

Take heed, protect and keep that stuff outside your homes.

I am no expert , nor do I play one on TV, but I would install a ground rod outside as close to my shack as I could. You can discuss rules an regs until you are blue in the face but direct to ground is good. I have mine that way , it is also with the house ground thru my surge protector. I also have my radio and computer power thru a relay set up and if I lose power in this rural area, the relay drops out and nothing will power up or reboot unless I press the reset button. The main relay is a 4 pole and it supply?s it?s own solenoid thru a pole, with a panic button and reset button. This way my satellite internet uplink modem , printers and things are all off line if I am not home and there is a storm.

Hi all of the list,

Someone that work or have worked with G5RV antenna can tell me what´s the better type of ladder line to use in one G5RV in inverted V config?

The question is, 300ohm or 450ohm???

That´s all and thank´s a lot.

It won't matter as long as it is the proper resonant stub it needs to be. The length will vary depending on the velocity factor of the line.

I would go with 450 Ohm and follow this link as it explains how to get it just right as far as the length goes through testing with an analyzer.

http://www.vk1od.net/G5RV/optimising.htm

Owen has a lot of great info on that site in general.

From: Richard Schmuke
Topic: 6089 Message: 6163

When I disconnect the feed lines it is after they have gone through a coax switch set to ground and before my SWR meters so the coax is grounded and the rig is not connected. I set up my relay system for power after listing to my scanner, laser printer and inkjet printer restart several times during a storm. Being in a rural area the Co-op power grid is not the best when a storm comes through but they are nicer to deal with when there is a real problem than the big power company in the city.

I would also add to go for the stranded 14ga 450 Ohm and not the solid core. The solid core stresses when bent and will break fairly easily from repeated movement.

6167. Lightning protection - off the subject of ham radio.

Yahoo group: ham-antennas (2008)
Date: 2008-10-02 17:26:10 UTC
From: vaclav sal
Topic: 6089 Message: 6167

?
I very much enjoyed and learned a lot from the current discussion on ham equipment protection against lightning strike.
I recall an article in QST that described in details what direct strike does to anything metallic in its path.
Since I moved to Texas I have experienced few "severe weather" thunderstorms.
What bothers me - the lightning rods, so common in my country of birth are nonexistent here!
The irony - the only true lightning rod protection can be seen on church in Texas ghost town of Praha! (I was born in Czech town of Praha!)
The other sites using lightning rods are electrical substations with ?vertical antennas?.
?
It is my understanding that lightning rods actually prevent direct strike by discharging the static electricity buildup before it becomes high enough to cause the big spark.
?
Would be nice to hear story about direct strike into ham shack e/w lighting rods.
?
I would like to add my favorite Mark Twain quote?
?The thunder is bold and noisy but it is the lighting who does the work?
?

Vaclav,

To answer your question below, you are correct. That is what a lightning rod tries to do. They were invented by Benjamin Franklin. It gives a path to ground to dissipate the ionization, which if allowed to build would discharge in a spark.

It is debated whether they are more effective when made with a sharp point or if they still work with a dull point. I tend to favor a very sharp point myself.

I see lots of lightning rods here in Las Cruces, NM. Mostly on high rise buildings. The power company also uses them on the steel towers used for the power grid.

Correct Steve, the sharper the better as it increases the... oh, call it tension, the intensity of the electric field by concentrating it at the point.
I'm trying to remember where, but very recently I saw a device which looked like a metallic softball studded with... oh, looked like two inch sharpened spikes, like an enraged porcupine. The demonstrator declared that it was more effective than the single point... but I'd not want to test it here. ;-)

Vaclav,

To answer your question below, you are correct. That is what a lightning rod tries to do. They were invented by Benjamin Franklin. It gives a path to ground to dissipate the ionization, which if allowed to build would discharge in a spark.

It is debated whether they are more effective when made with a sharp point or if they still work with a dull point. I tend to favor a very sharp point myself.

I see lots of lightning rods here in Las Cruces, NM. Mostly on high rise buildings. The power company also uses them on the steel towers used for the power grid.

Yea, seen those installed. The one on the TV tower on Sandia Crest was closer to 10" in diameter. I discribe it like a kush-ball.

The company that makes those says they garantee it's efectiveness, but I can not for the life of me remember who makes those.

I think I would go with a good quality single lightning rod on the tower, and several around the parimeter of the roof, especially at the peak. The one on the tower would have the copper strap to ground. On the roof I'd use what comes in the kit, which is sort of like copper wire rope, or copper braid with a hollow diameter of 3/4 inch.

I have seen where a building had these on it's roof, and a shorter building across the ally was the one struck. So, they must be somewhat effective.

At an FM station where I was CE, we got hit by multiple strikes during a very severe thunderstorm. The lightning rod must have taken quite a few hits. It was so badly burned that the top 10" or so was gone. That station's auto-logger showed 21 power drop-offs. I figure that is the number of strikes we took. The station next to ours lost their antenna and a feed line. The 3 1/4" coax melted in two in a couple of places, and the whole coax from the antenna to the drip loop was split. I figure the current was so high that it heated up the coax gas (nitrogen) and caused it to burst. We normally keep 3-4 PSI charge in the coax so that it never sees a negative pressure and sucks in moisture.

Sandia Crest is at 10,678 feet, plus the 200' tower, really puts the antenna right where the stuff wants to discharge. You really need to be on a mountain top during a TS for an experience you'll not likely forget any time soon.

The use of lightning rods appears to be very dependent on where you live. I grew up in a town in Connecticut where all the houses had them. Then in Massachusetts I noticed none of them did. Then moved to another town in MA and saw that many of them did. I remember even being told that tree branches over your house protect it from being hit, negating the need for lightning rods. (But then why is it so bad for people to take shelter under a tree, and why do so many people die doing so?!)

I believe that the question of rounded vs. pointed lightning rods remains highly debated, to this day in some circles. I've read it is even outlawed in some states to have one form or the other. (Not that those particular ancient laws are still observed.) I think that the theory of the rounded ones is to not use a point (which concentrates the electric field and actually encourages a lower level discharge at its point) on the theory that it might cause or somehow encourage a lightning strike.

> Would be nice to hear story about direct strike into ham shack e/w
> lighting rods.

Sorry, no experience I can share. But I've read some interesting stories about hams who disconnected their feedlines (but didn't ground them) and then saw significant sparking and/or corona-like glows around them.

A direct strike typically burns your house down. It probably also melts your rig, not that it matters since everything goes up in smoke anyway. The amount of energy released by a direct strike is virtually impossible for your house to survive, which is why lightning protection is intended to *prevent* strikes, not absorb them.

Andy

One of the trade names I heard was "Static Cat"

The theory is that with a good ground and a GOOD conductor up the tower to these static balls is they allow the lighting to discharge thru them and not the tower. The idea was explained to je as the static charge between ground and the clouds build, the electricical charge flows to the points of the ball and then arcs over to the cloud. Thus by semi controlling the route it avoids our precious equipment.

My days in broadcast engineering I saw several of these. The ones that worked had very good ground systems around the tower and a large low impedance conductor up the tower. It requires much more than just a few ground rods for it to be effective.

And before Im flamed, the US Navy had reports about lighting: Some lighting goes from ground to cloud, some goes from cloud to ground, and then the third goes from cloud to cloud.

I think too many think the ground rod does the work. My professional opinion is this: Its the surface area contact with mother earth that gives us a ground. The ground rods provide a large area of contact but often its the bare conductor buried below the sod that actually gives the better connection.

If you are using one ground rod and a small conductor and think thats enough ground, Ill smile and say "nice fuse"

Ahhh Andy, a very good question... 'scuse me while I pounce on it! ;-)

Contrary to intuition, when a lightning stroke is dissipated into the ground, it doesn't just disappear. (Ground ain't really ground.)
It forms a gradient, just like the voltage drop experienced along a piece of wire conducting a large current.
So, coming from the tree's base (the area of highest potential) out a foot or so, you'll see a reduction in amplitude. And, so forth for each extra unit of distance from the tree.
Think a bunch of series connected resistor strings, all in parallel radiating from the strike point in all directions.
Cows standing in a field in the immediate vicinity of a strike have been electrocuted (so I"m told) because they were facing toward or away from the point of the strike. The reason given was that the voltage difference between their front and rear feet was sufficient that they became part of the circuit and the shock stopped their hearts.
So, when you hunker down in a field like you're told to when you feel the hair on your arms raising as a precursor to a strike, make sure that you face toward or away from the highest object (which might be the point of the strike)(like you're going to remember all this stuff anyway ;-)).
Oh, and keep your feet close together.

This plays into another point: Why use more than one ground rod to get rid of the blast? Well, because of that gradient effect.
Having more properly spaced rods will conduct the strike into a larger area, effectively reducing the "work" each parcel of ground has to perform to get rid of the energy.

Ohhhh!

Another "why not under the tree" I've heard of is that if you're close enough to the trunk, the lightning might "side flash" over to your more conductive body... OUCH!

73, and "watch out for that tree!"

Stan

We either need some "mad scientist" or real experience with lighting rod or ball strikes.
?
Here is my part of reality.
?
When I first got into this hobby we had a commercial RX in our club station.
It had a neon tube, regular NE2 variety size of common glass fuse, connected directly from the antenna terminal to chassis ground.
We run a full size 80 meters Windom and during the lightning storm this neon flickered?with each strike near by. We never got a direct hit! And our only ground connection was to AC power outlet!
?
This experience proves, at least to me, that "size does not matter". As long as the discharge current stayed within the few mA of NE2 ?spark?. It also proves that the static potential is being discharged from the antenna area as soon as it gets above NE2 ?firing voltage? - somewhere bellow 100V.
Far cry from real lightning kilovolts!
?
I have observed similar setups on open wire telephone line strung along the railroad tracks.
?
So, the moral of these stories ? the lighting rod protection works. If you are from Missouri put a NE2 neon bulb from your antenna to ground and watch the minifireworks.
?
?

Stan,

I have a different theory. My thought is that the tree is the primary of a transformer, and your body becomes the secondary. Since their is such a large current pulse flowing through the "primary" this air core transformer will produce a very large potential on the "secondary" of this transformer. Because of the internal resistance of the human body, it absorbs some of the current induced on the secondary and this energy has the potential (pun well intended) to destroy tissue. This can kill the poor victim.

In the early 1990's there was a girl killed on Sandia Crest, just out side of Albuquerque, NM when a lightning strike hit the southern-most tower. It induced a lethal voltage on the handrail of the lookout located about 200 yards to the south.

Y'know, Steve, I was going to posit that same thought, but wasn't sure if my surmise would hold water. (I had mentioned the transformer action as regards the down lead of a lightning rod system and the adjacent house power and signal wiring.)

Thanks for taking the lead on that.

Stan

6180. Hustler vertical -no radials

Yahoo group: ham-antennas (2008)
Date: 2008-10-03 18:55:17 UTC
From: dalepavlicek
Topic: 6180 Message: 6180

Here is my question,unless I want to dig up my pool and drive I have NO way of putting down the required radial field for a vertical like the hustler. Iam Interested in 40 meters for the vertical,have everything else covered with a 6 band hex beam. I thought about the sigma -40 vertical dipole ..big cost ,plus they are not building any for a while. I was putting in several light poles behind the house,next to the boat dock,dug the holes about 24 " deep and before I got the cement ready they filled 1/2 way with ground water. I asked around and was told thats the reason in sw flordia,there are no basements. Keeping 40 meter as the lowest band for the vertical, what would be the chances of decent performance for the hustler using a ground rod system for the antenna?? considering the high water table? Anybody have any other ideas they can offer for a vertical..don't want to use a gap or cushcraft with a huge counterpoise.
thanks for reading.

From: Chris
Topic: 6180 Message: 6181

The GAP titan is mediocre on 40m, I have one, but the counterpoise is hardly what I would consider huge, roughly 72" across or so. It has to be a lot smaller than a hex beam is. I simply pole mounted it high enough to walk under it while mowing.

I would really recommend a wire antenna instead though. Something like a double extended Zep or a double bazooka cut for 40m would work quite well, better than the GAP titan DX for sure. My 135' wire outperforms it on 40m consistently.

If you want vertical polarization a delta loop, fed properly would also be quite manageable for 40m size.

stan,
if you take it to the logical conclusion, when you feel the hair stand up on your body and youre near a tree, stand on one leg. that way you will only get your foot barbecued!! better to be peg leg the pirate than chuck the conductor!

I am even less of an expert, having my license only since yesterday...
(HI)

I am new to the group, and I am very happy to see this group here on
Yahoo. I was an Advanced class Ham (KC8VI) back in the Mid 80's
through the early 90's, then let it slide.... just recently got the
'bug' again, so went to a VE session on Saturday, took some tests..
and here I sit. This time around I want to do more building and
tinkering, and less sitting on traffic nets, etc. I want to do some
QRP work, and that, of course, means a strong emphasis on good antennas.

I agree with Allan, but would add that some ferrite beads (3-5 or so)
around the coax at a 1/4 wave and a 1/2 wave away from the feed point
would help also. Remember to take the coax velocity factor into
account when calculating the distances.

Everybody has there own situation and physical surroundings to deal
with, but if I were putting up that antenna, I would turn it 90
degrees, put one end about 35" up in the air, attach the other end
near the ground, run a 1/2 wave feedline (center fed still) off
towards the ground at about a 45" angle, with 3-4 ferrite beads around
it. At the halfwave point, I would drive a ground rod or two into the
ground, and ground the braid of the coax there, then run good coax
from there to my rig. Cheap, easy, low RF coming into the shack, very
low radiation angle... Right out of the ARRL Antenna book

Oh.. and not near the power lines either.

However I made a 20m dipole and fed it with some cheep RG58U, This
caused RF in the shack and this was resolved by replacing the coax
with much better screened RG58A/U and a choke at the antenna feed (20
torroids over the coax as discussed here http://www.dx-wire.de/brit/).
My RF problems are now sorted.

Dave, how tall is the tower that your beam is on?
At the OCARC's (Orange County Amateur Radio Club) field day site this spring we loaded up a 40 (+/-) foot flag pole on 40 mtrs. using a simple shunt feed system and a "T" match (two caps in series with an inductor to ground at the cap to cap junction).
IIRC it was featured on the ARRL's site a few months back.
Funny thing, it actually worked rather well for a simple non-grounded piece of fat aluminum pipe stuck up in the air.

Subject: [ham-antennas] Hustler vertical -no radials

Here is my question,unless I want to dig up my pool and drive I have NO way of putting down the required radial field for a vertical like the hustler. Iam Interested in 40 meters for the vertical,have everything else covered with a 6 band hex beam. I thought about the sigma -40 vertical dipole ..big cost ,plus they are not building any for a while. I was putting in several light poles behind the house,next to the boat dock,dug the holes about 24 " deep and before I got the cement ready they filled 1/2 way with ground water. I asked around and was told thats the reason in sw flordia,there are no basements. Keeping 40 meter as the lowest band for the vertical, what would be the chances of decent performance for the hustler using a ground rod system for the antenna?? considering the high water table? Anybody have any other ideas they can offer for a vertical..don't want to use a gap or cushcraft with a huge counterpoise.
thanks for reading.

Im looking for the coax length of the balun on a VB-28FM and the hairpin length too ....

Its listed as belden 8259 (50 ohm coax with velocity of .78) the coax really needs replaced, it is just falling apart.

Elevate the antanna a few feet (5 would be ideal) then run two elevated radials for every band you want to use it on and the antenna will work beautifully. The radials don't have to be straight... bend them any which way you wish. Run them so they don't bother the pool. You can experiment using the hustler without radials.. if your ground is good enough it may play well. Moreover radials can be any length on the ground... more is better and longer is better, but shorter is better than none.

Option #2 run a buckmaster wire antanna off your tower should you want multiband coverage. Otherwise just run an inverted V off the tower. Even fairly low an inverted V can be a very effective antenna. In my experience wire generally beats aluminum.

I have the Sigma 40 . Works Ok but no better than my Hustler over very poor ground. If you want to try one they are easily made from wire with a bit of coil loading. I've used my Buddipole equipment (coils) to make one.

6190. Delta match on a half-square?

Yahoo group: ham-antennas (2008)
Date: 2008-10-04 14:05:42 UTC
From: Bruce Conner
Topic: 6190 Message: 6190

I'm thinking of putting up a half-square as a single band antenna, but I have a moderately long run to the shack and thought it might be better to run window line to reduce the loss for my QRP station. The half-square feedpoint is nominally 50 ohms, which is great for coax, but I got to wondering if maybe a delta match would work for the 450 ohm window line. That way I could use a single piece of wire for the antenna too, and avoid baluns, center insulators, etc.

I've never tried to calculate or model a delta match before, and the only examples I can find are for a simple dipole with the wires sticking straight off from one another. The top corner feed for the half-square would, to me at least, seem to present a different model since it has a 90 degree angle. (this is a "tails down" version of the half-square with the phasing wire on the top)

I'm still pretty new at antenna modeling software, so any help on figuring out how to put this into MMANA would really be appreciated. Is there any way to set up the antenna wire shape alone, and then deduce the correct points for attaching the feed for a 450 ohm delta (or T match). I can't seem to figure out how to know what the impedance is at any given distance along the wire, but I know the answer is staring me in the face.

Hi Chris and Steve!

Steve I am still using Win 2000. I don't have enough memory to run Ubuntu
yet

Chris I downloaded the program and applied for MM-HAMSOFT yahoo group.
Thanks for the help.

Now on to lightening rods! How would I do that with a wire antenna. I have a
G5RV up about 37 feet. Currently I just unplug the ant when I am not using
it. However at my age I don't always remember to do that.

6195. Antenna Good/Bad Weather Rule???

Yahoo group: ham-antennas (2008)
Date: 2008-10-05 13:33:45 UTC
From: Randy McKenzie
Topic: 6195 Message: 6195

OK, I admit it, I broke the rule and had to pay the price!

Saturday was a wonderful day here: sunny, low 70's, clear skies, and I finished my "honey do" list by 1pm.....So of course I decided to experiment with some antenna items.....

I have collected several parts from antenna projects over the years: A old HF vert, a broken 6M, and some odds and ends AL sections.

The idea was to use the odd parts and create a simple ground plane for 20M. I made some wire ground radials earlier this week....added the four radials to the base of the mount.....

I found that the tubing would work together and the first adustment put the vertical radiator at 16.5 ft. Should work OK and then tune from there right? Such a nice day, the birds singing, so comfy, even had a cool drink admiring my idea.....

Assembly was using a old tripod, mounted onto a old pallet, and a 10ft TV mast. The original HF mount was used and it already had a SO239 for my coax. Simple basic ground plane, 10ft off the ground right? Should load nicely.....so I gathered my coax and MFJ.

SWR was terrible! Lowest anywhere was 4 to 1 at 6mhz. No way a ground plane wouldnt load right? So I took it down and started pondering.

I ended up tearing the base connector apart to find a blown up loading coil and corroded connections inside the insulator. So I cut all this out, replaced it with a simple jumper from the center of the SO239 to the element. Years ago the HF antenna was givien to me, now I know why!

Then the wife got back home, ending the playtime....."What in the world is all that mess?"

My plan of attack is to try it again today: Sunny, 70's and clear skies. Watch for the mushroom cloud over southwest VA.....

Im begging for trouble again, I just know it!!!!!!!

having the feed line horizontal shouldn't affect the antenna that much if you can get it close to a right angle to the elements but you can not coil it this will dramatically change the impedance if the feed line. You must keep twin lead at least twice the width of the line distance from any metal 450 ohm ladder line is one inch wide so two inch distance minimum more would be better.

6198. loop updates & phasing without a phasing unit

Yahoo group: ham-antennas (2008)
Date: 2008-10-05 13:59:10 UTC
From: DAVID
Topic: 6198 Message: 6198

hi and sorry if you are getting bored with the antenna updates but i spend more time tweaking/making antennas than i actually do listening.

the story so far the 7 by 6 feet multi turn loops are now down i have 2 single turn loops 1 nw and 1 w and yes even at that the difference is amazing.

both are fed with a 48/11 turn overlaping baluns and each has a 1000 ohm resistor in the opposite corner.

i cant get over the back rejection on these antennas i put a switch on the nw loop at the resistor so its inline and off and i sent my freind some clips of what it can do ie slovenia on 918 khz when the resistor is open its a s9 but put the resistor in use so the main lobe is nw its either not there or very weak in the noise and i think my friend is going to make one as well and join the group.

the next thing i am going to do is setup a series of switching so i can have all the directions just like a k9ay loop not to bad for antennas in the attic.

PHASING WITHOUT A PHASING UNIT

IF I PUT A SMALL 1X1 MULTI TURN LOOP WITH A TUNING CAP IN SIDE MY FLAG/LOOP AT THE FEED POINT OR RESISTOR I CAN EASILY NULL OUT STRONG LOCALS IE RADIO SCOTLAND

ON 810 KHz AND GET EUROPEAN SIGNALS. I MUST POINT OUT THAT THE RESISTOR IS IN THE OPEN POSITION IE NOT IN USE THIS SAVES ME BORROWING MY FRENDS MFJ ALL THE TIME LOL

I ended up tearing the base connector apart to find a blown up loading coil and corroded connections inside the insulator. So I cut all this out, replaced it with a simple jumper from the center of the SO239 to the element. Years ago the HF antenna was givien to me, now I know why!

Then the wife got back home, ending the playtime.... .."What in the world is all that mess?"

My plan of attack is to try it again today: Sunny, 70's and clear skies. Watch for the mushroom cloud over southwest VA.....

Im begging for trouble again, I just know it!!!!!!!

From: Sam Cook
Topic: 6193 Message: 6200

I am running a G5RV at about 22ft in inverted-V with the twinlead stub/feedline HORIZONTAL. It is secured to a dacron line from the mast over to my tower, 75ft away. Been up for a couple of years.
I "design by dumb" and still get good signal reports. (I just do things without much engineering.) Have talked to Hawaii and Mississippi on it as well as local (~300mi) NVIS here in state of Missouri. Haven't tried it for DX.

If you can get the SWR low enough, sure it'll work. It'll work LOUSY, but it'll radiate a tiny amount of RF.

Personally, I wouldn't waste my time on it. you can always pick up a CB antenna at a truck stop and trim it for 10 meters.

My question was meant as a rhetorical one.

Thank you, Stan, for filling in a good explanation.

I once heard that some baseball players got struck while playing a game (not
the big leagues). Lightning hit the pitcher, who was killed. The rest of
the players got knocked on their asses but survived. If the story is true,
it helps illustrate the "spreading out" effect.

Betreff: [ham-antennas] Delta match on a half-square?

I'm thinking of putting up a half-square as a single band antenna, but
I have a moderately long run to the shack and thought it might be
better to run window line to reduce the loss for my QRP station. The
half-square feedpoint is nominally 50 ohms, which is great for coax,
but I got to wondering if maybe a delta match would work for the 450
ohm window line. That way I could use a single piece of wire for the
antenna too, and avoid baluns, center insulators, etc.

I've never tried to calculate or model a delta match before, and the
only examples I can find are for a simple dipole with the wires
sticking straight off from one another. The top corner feed for the
half-square would, to me at least, seem to present a different model
since it has a 90 degree angle. (this is a "tails down" version of the
half-square with the phasing wire on the top)

I'm still pretty new at antenna modeling software, so any help on
figuring out how to put this into MMANA would really be appreciated.
Is there any way to set up the antenna wire shape alone, and then
deduce the correct points for attaching the feed for a 450 ohm delta
(or T match). I can't seem to figure out how to know what the
impedance is at any given distance along the wire, but I know the
answer is staring me in the face.

73,
Bruce

I've got a dual band mag mount antenna that seems to work OK. It's 2 and 6 meter, though, and it's about a four footer. I don't see a 16 inch antenna working well much beyond the 2 meter band. I'm not in Mr. Cebiks league on antennas, however so someone else may give you a more optimistic view.

Anyone who has a guyed vertical, or who has worked at an AM radio station, probably knows that the guy wire egg insulators start arcing and sparking as a storm approaches. The sudden electric field from each strike, miles away, induces voltages in the guy wire sections, enough to overcome the breakdown voltage of a few inches across the insulators.

Many years ago I was halfway up on a broadcast tower when a storm was still more than 10 miles away at its closest. My co-worker and I started hearing buzzing noises with each distant strike, and when we looked at the insulators, we could see the little sparks. It was, well, interesting.... (In retrospect, we probably should have climbed down when the storm was still 50 miles away.)

Gas discharge tubes are often used to suppress stray voltages. I wonder how different they are from ordinary NE2 neon bulbs.

Bill , I make all my antennas , that is my main part of the hobby , but I am mixed up when you ask about a mag mount and dipole/jpole and ladder line in the same sentence. Ladder line makes nice and neat / cheap J-poles and slim jims but not with a mag mount. Where are trying to set this up , house , car ????

The difference is in the amount of current and the firing voltage. I
think NE-2's fire at about 70 volts, but that is without the uranium
starter. They poison some types of neon lamps to make them fire at a
little lower voltage. Some lamps are made with argon and another gas
used is krypton. They even cascade some arc plugs to make the voltage
higher.

One thing that a lot of people forget is when these arc plugs fire,
there is contamination of the terminals on the inside of the plug caused
by erosion from the current and this can contaminate the plug. You
should count on having to change the plugs every so often. I change mine
in the spring each year, along with the smoke detector batteries. If you
are using those spark gap types, you really should replace them too. The
discharge will ware away the point on the screw, and then it won't fire
as easily. All cheap insurance.

Yes, it's not the voltages, it's the potential differences between two or more points that causes the damages. Everything must be strapped to the same potential.
In our work we deal with school buildings' fire alarm and intercom systems. Schools are made up of seperate buildings all tied together by fire alarm and intercom wiring. Potential voltage differences from the main admin building and remote wings cause the problems with storms. We typically have sandy soil with poor conductivity here in central Florida. I have been fighting the argument that within even the metalic rigid conduits that interconnect the wings' wiring I wanted a heavy ground wire to be along with them and bolted to the terminal cabinets at both ends.

I think the NEC would go along with a Bonding
Cable (#6 or heaver) between your Shack Ground
and the Power Entrance Box.
As long as all things are Bonded together you should
have No Difference in Potential between the grounds.
Also, Remember that your CATV and you Phone
should also be bonded to the same ground.
Clamps under ground will corrode and should be
welded or brazed ...
Tie your tower base grounds Also into your new
system ground.
I worked in cellular and even with many hits on the
towers the equipment kept working with Good Grounds.

i can see where 10 m is close resonant to the 2 meters....but not a 2 meter antenna resonant to 10 meters.
the 10 meter antenna would be a multible of the 2 meter..posible of some gain!

Sam,

Thanks for the encouragement!

As I posted Danny, it may take a couple of runs, bit I think I can manage this...

Phil (and Others),

Not to gnaw the issue, but when y'all say ALL things should be centrally grounded, are you saying ALL things as as in not just all transceivers, antenna boxes, and power supplies, but ALSO EVERYTHING as in Keyers, SWR meters, speaker boxes, power distribution panels, and all the other little pieces that eventually fill the Desk?

6220. New end fed random wire antenna

Yahoo group: ham-antennas (2008)
Date: 2008-10-06 15:40:45 UTC
From: Al
Topic: 6220 Message: 6220

This weekend I put up a 144' end fed random wire, with 1/4 wave counterpoise on each band. Installed a new MFJ-974HB Balanced (& Random wire)Tuner.
Can't get it to tune up on these bands wich have 1/4 wave counterpoises installed 16" above grade, 10, 15, 20, 40, 80 & 160m. Looking for suggestions.
Tnx, Al

I don't have exact math for you as to why this isn't working.

I am curious, with a balanced line tuner like that, why didn't you just cut that 144' wire in the center and feed it with 450 Ohm window line or similar balanced feeder? It would work just fine 80m and up and be very low loss. That would be what I would do right away if you can physically manage that layout.

I've had very temperamental and mixed results end-feeding wires. Lots of RF issues and the tuning range has always been *very* narrow. It has always been a tricky tuneup with a very narrow range of adjustment to achieve tune. My only other idea is whether you have enough experience with a manual tuner to 'catch' the tuned point or if maybe you are just missing it.

When I say narrow, it's just barely a nudge of either the capacitor or the inductor to get it tuned. A tiny nudge in either direction of either one and it's gone again. With a balanced system, the 'play' in adjustment is far wider and sometimes it's actually hard due to lack of meter movement to determine where the sweet spot really is because the match range is so broad.

Norm it's not so much that the system is "centrally" grounded, but that it is all bonded together.

Again, think of your entire shack as a kid jumping rope. The body jumps to let the rope pass beneath, and likewise the ENTIRE installation should be able to do the same. The whole of your equipment may rise to several thousands of volts above earth potential for the instant that it takes to dissipate the stroke energy, but any piece of equipment will see all the rest of your equipment as being at the same potential... so no destructive current flows... through any of it... outside might be another matter, but all your stuff is safely inside the enclosure that you built to protect it.

That's accomplished by bonding everything together and bringing in ALL the services: power, telco and antenna leads, through ONE portal, the "entrance panel".

So, should everything be tied to your grounding system? Yes, but since some of the devices you mentioned... say the keyer, if it draws it's power from the rig, is already tied in. Similarly the SWR bridge is already tied in because it's connected to the grounded coaxes. If it has a wall wart (wall transformer) to power the panel lamps and meter amplifier, if so designed, the wart has to be plugged into the power strip (that you mentioned) which is also bonded to the grounding system.

The hardest part is in dealing with the services because they often come into the building at different points of entry. So bonding them together in such a way that the amount of energy which runs through the equipment and through the actual wiring (be it the green safety wires or the telco's red ground wire) is kept to the barest minimum, takes some engineering and the ability to stand far enough back to see the whole building and all of it's wiring as one entity.

The "centrally" part more looks at where the actual earthing system: rods, bonding strap, etc. is situated and how they relate to the services that are being grounded. For best effect (expecting that the antenna will be the point of entry of the strike) the actual earthing system (ground rods and connecting strapping) should be as close to the point that the coaxes and rotor wires enter the shack as is practical.
If, OTOH, the strike enters through the power company's wires, the low impedance bonding will conduct the bulk of the energy around the power distribution system to your grounding system, keeping from frying the wiring in the walls. One of the mechanisms that enables that to happen is that the power wiring in the walls is typically more inductive than the nice wide strap used to accomplish the bonding. Lightning, like all electricity, while being tremendously powerful, is also infinitely lazy and always takes the path of least resistance (for us, impedance).
To us, sometimes it might not look to be so, but post strike analysis will usually reveal the "why" of the of the path taken.

OK, nuf words... typing switch set to OFF, off state begins... in six, five, four...

Also, (and I meant to bring this up before) a 16 inch stinger is not resonant on 2-meters, therefore I assume there must be some loading at the bottom or in the center. That would make it even worse on 10.

OTOH, a 10 meter quarter wave is about 5 1/4 wavelengths on 2... so it MIGHT work.

6225. Re: Delta match on a half-square?

Yahoo group: ham-antennas (2008)
Date: 2008-10-06 21:10:43 UTC
From: Bruce Conner
Topic: 6190 Message: 6225

Hi Sigi,

Well, I'm sure we could send this list into a long discussion of what is a half-square vs. what is a bobtail. Most writers (including LB Cebik) call it a half square if it has only 2 legs, with the phasing line on the top OR the bottom, and normally use the name bobtail for the 3 legged version. I think it's just a matter of nomenclature, as they are all related and were invented by the same man. No big deal! ;')

I actually have the antenna well modeled in MMANA as a standard 50 ohm coax feed, and it looks very good in that form (nice TO angle and gain). But as an exercise (and for practical purposes), I'd like to try feeding it with a 450 ohm window line to a delta match rather than use 50 ohm coax. That was actually my question; how to set up the delta match in MMANA. I'd be happy to send you the file of my current 50 ohm model if you think you can change it so it will work with the delta match!

I think the confusion for me is how to handle the multiple source points, since it's a balanced feed with some amount of distance between the two connections rather than a single 50 ohm source. The things I have tried in MMANA didn't seem to work the way I expected, so I must be missing some critical bit of information on how to set up a parallel line feed for a delta match connection.

Let me know if you'd like the file, and I'll email it to you. Thanks!

73,
Bruce

Have to laugh at your tag, you think it is hard when ground water is 10'
or less from the surface? Try it here in NM where ground water is
sometimes in the 1000' or more below the surface. Soil conductivity
during the drought was measured here in the mega ohms. But it is still
needed, unless you just like to have sparks dancing in your home.

I do ground everything that has a metal case, and if the manufacturer
didn't make provisions, then I have drilled and tapped threads for
screws to facilitate grounding. I have in my shack a 3" wide copper
strap going to the ground rods (3) that are 8' copper clad steel shafts
imbedded 7 1/2' into the ground spaced 2' from the tower in an arc
equally spaced in 180 degrees. The tower is bonded to the ground rods.
Everything is soldered together using 50/50 solder. The DC resistance
from the farthest piece of equipment to the tower is .077 Ohms measured
with a 6 1/2 digit 4 wire Ohm meter.

Elmo's fire. That is what they call it when you are in the building on
the mountain top, lightning strikes, the lights go out and you see a
beach-ball sized blue haze coming at you. I made the mistake of kicking
it, but it knocked me on my butt. Hurt like a %&*#$. I thought I was
going to die. And I don't know that I moved it any. I think it just
discharged through my leg. All I know is I won't ever do that again. I
am told mine was a little one, and that a really dense one can kill.
Supposedly a dense one really glows bright enough to see in broad daylight.

Nope, not talking about St Elmo's fire, talking about a full-strength
bolt hitting perhaps 100 yards in front of the nose and sounding like a
howitzer just went off. I departed the pattern top the north and landed
20 miles form the thunderstorm and waited it out.

To: ham-antennas@yahoogroups.com
Subject: [ham-antennas] Re: Delta match on a half-square?

Hi Sigi,

Well, I'm sure we could send this list into a long discussion of what is a half-square vs. what is a bobtail. Most writers (including LB Cebik) call it a half square if it has only 2 legs, with the phasing line on the top OR the bottom, and normally use the name bobtail for the 3 legged version. I think it's just a matter of nomenclature, as they are all related and were invented by the same man. No big deal! ;')

I actually have the antenna well modeled in MMANA as a standard 50 ohm coax feed, and it looks very good in that form (nice TO angle and gain). But as an exercise (and for practical purposes), I'd like to try feeding it with a 450 ohm window line to a delta match rather than use 50 ohm coax. That was actually my question; how to set up the delta match in MMANA. I'd be happy to send you the file of my current 50 ohm model if you think you can change it so it will work with the delta match!

I think the confusion for me is how to handle the multiple source points, since it's a balanced feed with some amount of distance between the two connections rather than a single 50 ohm source. The things I have tried in MMANA didn't seem to work the way I expected, so I must be missing some critical bit of information on how to set up a parallel line feed for a delta match connection.

Let me know if you'd like the file, and I'll email it to you. Thanks!

Hello,

So I was curious about the hamstick 10 meter 2 meter theory so I did a test. The test was using a MFJ-259B, a ft-817nd, a 10 meter hamstick sitting in my pickup in the driveway. On 10 meters the swr was 1.2 - 1.5 : 1 across the 10 meter band. On 2m meters the swr was 1.4 - 1.7 : 1 across the band. No problem bringing up the local repeaters. One further test I decided to try was bringing up a few 440 repeaters. Using the swr meter on the ft-817nd the swr was 2-4 bars and it did not trip the high swr warning light. It worked also. Don't know if this helps anyone but I thought it was interesting.

When I was a Novice, 1960, I was tuning up on my foster father's dummy
load, a couple of 150 watt bulbs in parellel. I heard a KH6 station
calling CQ near my crystal frequency, and responded. We made contact,
both giving each other 559 reports. He was running 50 watts to a dipole
and I was running 30 watts to a, oh no, can't be, a pair of light bulbs!!!

I switched to the antenna and we continued the QSO. I have a QSL card
here somewhere to prove it.

Point is, you really only proved it is a little better at radiating than
a dummy load. How about some actual field strength measurements?

Hi Steve,

Field strength mesurements are not required if it does the job you want it to do. The original question was somebody want to know if a 2 meter antenna could work on 10 meters. Somebody else posted 10 meters should work on 2 meters. I just proved that it would work. Yes even dummy loads will work too.. The point is for a technician license holder or anybody else that just wants one antenna on their vehicle that they might give it try. For me it much simpler than two antennas.

Not only field strength, but some vertical radiation patterns as well. Multi-wave antennas have odd patterns which tend to have high radiation angles. Good for talking to repeaters, up close, on very high hills... oh, and airplanes. The amount of loss, especially at UHF, in the hamstick would also be of interest... but, hey, in a pinch, thanks for checking out the idea!

Stan

6240. Balun connections

Yahoo group: ham-antennas (2008)
Date: 2008-10-09 14:40:44 UTC
From: Norm Blitch
Topic: 6240 Message: 6240

I am under the impression that given a simple home-brew 1/2 wave wire dipole, the use of a 1:1 Balun is better practice that just connecting the wires to a coax female and calling it a day...

Assuming that this IS correct (and please DO correct me if the above is WRONG), is there any elegant or at least passable way of TEMPORARILY connecting the wire elements to the Balun for testing/evaluating?

Right now, I can't justify the purchase of a "Bakers Dozen" Baluns to play with all the wire antennas I am contemplating!

Sure. You can easily just wind the wires up to test with. You could also purchase a toroid or two and wind your own up. Not difficult at all. Or try using an "ugly" balun (loops of coax) to experiment with. Lots of ways to tackle this one. Good luck!

Hi, Norm, a Googling of the web for "coax balun" produced many hits, this among them;

http://www.bcdxc.org/balun_information.htm#Tim,%20K3LR

Towards the end, the construction info for an air wound balun is given... just about the cheapest way you can go.

good hunting,

Stan

Assuming that this IS correct (and please DO correct me if the above is WRONG), is there any elegant or at least passable way of TEMPORARILY connecting the wire elements to the Balun for testing/evaluating?

Right now, I can't justify the purchase of a "Bakers Dozen" Baluns to play with all the wire antennas I am contemplating!

I also have successfully used a 10 meter antenna on 2 meters. When I first was licensed in 1977, I cut a c.b. ground plane antenna to work on 10 meters. After i bought a 2 meter rig, an uncle who lived about 30 miles away wanted to work me on simplex. I could consistantly work him using the 10 meter ground plane up 40.' Although not optimal, the antenna did allow me to get on the air.

Hi, Norm, a Googling of the web for "coax balun" produced many hits, this among them;

http://www.bcdxc.org/balun_information.htm#Tim,%20K3LR

Towards the end, the construction info for an air wound balun is given... just about the cheapest way you can go.

good hunting,

Oh, just one thing... if and when you construct your balun(s), make sure to weather seal the exposed ends of the cable. Water WILL wick into the braid and WILL degrade its "solid tube" behavior, reducing it to a bunch of fine wires laid in parallel with each other. As a shield that s##cks and you want the cable to have a good working shield, that's part of the "why it works".
And, the water can and will wick several feet up into the cable... seen it myself when having to repair antenna mounts which had been ripped out of the roofs of school buses courtesy of high speed and low tree branches. Had to go back at least a foot from the open end to find shiny braid to do a re-solder job on.

Also, the stuff I used to use as a sealant was Goodyear rubber's Pliobond adhesive. It flowed down into the weave of the shield and stayed flexible for years of being out in the weather. Probably any good rubber cement will do. Or, even one of the "silicone" rubber bathtub, etc. caulks can be worked in to the weave, I've even used DAP's Urethane adhesive with good results.

One warning about the silicone rubber products; if you smell vinegar when it's squeezed out of the tube, you DO NOT want it on your cable! What makes that smell (acetic acid) is corrosive to both copper and the metals used to make up that nice silver tinning... nuff said!

I am under the impression that given a simple home-brew 1/2 wave wire dipole, the use of a 1:1 Balun is better practice that just connecting the wires to a coax female and calling it a day...

Assuming that this IS correct (and please DO correct me if the above is WRONG), is there any elegant or at least passable way of TEMPORARILY connecting the wire elements to the Balun for testing/evaluating?

> Elmo's fire. ...
> Supposedly a dense one really glows bright enough to see in broad daylight.

I've read little is known about them. Fascinating beasts. It is a rarity to have seen one up-close and, yes, interacted with it.

My father saw one in his childhood house, sizzling and "bouncing" down the staircase from the attic, leaving scorch marks as it went. Clearly visible in daylight, indoors. It reached the bottom step and exploded/dissipated.

I've seen other accounts that said when they explode, it can be like a bomb and can do serious damage.

My father's was in a house at a beach. Doesn't take a mountaintop (but I'm sure it helps). Saint Elmo's Fire was often seen in the rigging of sailing ships. In that case, the ship's mast is the biggest thing around for hundreds of miles so it's almost like being on a mountain.

One of those accounts from hams that I mentioned before, was someone who unplugged his feedline from the rig, but didn't ground it, and he saw a blue glow from the area behind his radios. It might not have been a full St. Elmo's Fire, but it was probably the same plasma that can form into ball lightning. That's why it's important to have a permanent lightning arrestor or ground strap, and not rely on manually grounding it.

6247. Balun with Yagi on VHF

Yahoo group: ham-antennas (2008)
Date: 2008-10-10 11:40:34 UTC
From: Kevin Morgan
Topic: 6240 Message: 6247

I have a question for the group regarding the use of a balun (coiled coax or otherwise) with a 2-meter Yagi. I recently converted an FM Yagi into a 2m beam and while doing swr adjustments to the gamma match noticed that I got way different readings depending on where the coax was in relation to the antenna.

Hanging straight down off the connector I was able to get a 1:1 match at 146 mHz, the frequency I was cutting for, but when I put the coax along the boom and down the support (pvc, the Yagi is sideways to the ground for vertical polarization) the swr jumped to 4:1 and the antenna became resonant at 149 mHz!

I put a couple of turns on the coax and wire tied it to the support mast and was able to get a 1.3:1 match at 146 mHz. I remember reading somewhere that Yagis are prone to feedline interaction so I'm thinking I need to incorporate a balun to stabilize it.

My question: What diameter and how many turns for this dirty balun?

Thanks for any help, I've been lurking for a while now and this is the first time I have posted.

Stan,

Thanks for the link!

Much to be learned here... AND it pointed out a possible flaw in my olde OSCAR antenna feeds; the "drip loops" prior to window entry were "random coils"!

Does the coax-balun NEED to be at the upper feed end, or can it be placed at the entry point to serve the additional purpose of the drip loop?

>were "random coils"!

Well, Norm, if those "random coils" are in coax, I'd expect to see no issue.
Coax length is what it needs to be to get where it's going.
If it's a bit too long and is rolled up, the only penalty would be a few
microDb of additional loss.

>Does the coax-balun NEED to be at the upper feed end, or can it be
>placed at the entry point to serve the additional purpose of the drip
>loop?

The balun, or choke should be at the antenna end.
The why, is that you're trying to reduce or eliminate RF being on the
outside of the coax which can distort your antenna's pattern and that's
where the RF would be spilling over from the inside of the shield to the
outside.
But, heres the catch, some antennas have benefitted from the extra element!
A horizontal dipole with a bit of added vertical polarization because of a
bit of RF on the shield of the vertical run of feed line. As long as it
tunes and doesn't upset equipment in the shack, it might be OK. Sometines
it can be a "crap shoot".

>73s, Norm

And to you as well!

I think what you are talking about would be similar to a fan dipole.

There is some interaction, but not so much that you can't use it. I have low bands on a similar idea. My 80 meter is loaded to also cover 160 meters, the 40 meter is loaded to also cover 75 meters, the 30 meter also covers 60 meters. I feed with a single coax at 38'.

Hope this is the info you are wondering about.

While I'll probably draw some fire, Norm, I don't see it as a problem.
Actually from a lightning mitigation perspective, possibly even a good thing.
The inductance of your "drip loop" would make that path to ground less inviting, especially if those cables were coming from an already grounded tower.
Of course, they wouldn't be a suitable replacement for the grounded entrance panel, more an augmentation.

hi all
I use a battle creek tri band vert/invert L
http://www.pi4cc.nl/link/mkII.htm

wire version
Coax fed
Ive got 40m tuned no worries
Ive got 80m tuned no worries
I get 160m tuned no worries

(all tests are done with MFJ 259B)
go back and check before packing up, 40 spot on
80, swr has gone up and ohms are into the 100's
Ive tried to retune 80 but with no difference,
3 mhz 25+ swr, 100+ ohms
4mhz swr reading 15 still 100+
the best I can get is 3 on 3.700 but still 100+ ohms

just for test reasons even after 2-2.5 foot has been trimed of swr
still the same and ohms into the 100s

so to sum up
I can have 40 & 80 ok
or 40 & 160 but not all 3

in easy explained terms any thoughts

many tnx

Norm, the two slopers I assume are fed at the top on the apex of a tower. In that case I would think the tower would "hide" one from the other,so probably no interaction. Now if you use a non metalic pole, I would think the passive one would act as a reflector to the then-active one.

Chris,

Tnx for the wise sugestion.
But, I wanted to get to know the end feed antennas for use when camping. I like the idea of being able to sling shot the wire up over a tree and not having to bother with any feed lines.
BTW, I'm sending the MFJ balanced tuner back and have ordered a Palstar BT1500A balanced line tuner for the horizontal loop.

6264. End Fed Zepp question

Yahoo group: ham-antennas (2008)
Date: 2008-10-12 19:42:38 UTC
From: Jonathan Helis KB5IAV
Topic: 6264 Message: 6264

I'm planning to build an end fed zepp for 20 meters. It will be a stealth antenna since I live in close quarters with my neighbors. I'm planning to put it under a wooden carport, but it may have to zig zag a little in order to get 33 feet of wire up there.

I don't have feedline yet and haven't found any twinlead locally, so I will have to order that or some ladderline. Any ideas on which would be better?

Someone suggested I could use speaker wire to feed it, not exactly 300ohm, but it might work. I already have 2 baluns and a tuner, so those things aren't an issue.

I like working PSK31 on 20 meters and my present antenna, a 60 foot half wave open loop in the attic is kind of hit and miss on 20. I also want to get some of the RF out of the house that antenna is giving me.

Never built an end fed zepp before, but I'm anxious to try.

hi when i was a novice most of us started with end fed sepps with what ever we had for lead in wire which in itself was part of the antenna , i used 124 feet of copper wire out the window to a 16 ft pole across the small canyon and on forty worked VK for my first DX arill have the card using 10 watts or less with a one tube homemade transmitter and the only crystal i had, the point is end fed antennas work and our tuners was a single small variable condenser with a light ble to tell me when it was tuned up ,

go for it you might be suprised
good luck
jerry

John, might you be able to make it into a dipole?
My reasoning is; the center 1/8 (each side) wave could be straight and the rest zigged and still have a reasonably directive pattern and you wouldn't need to futz with the fifteen feet of twinlead, just go with your 1:1 balun and do coax. The coax wouldn't be as bothersome for how it's run, where the twinlead doesn't like running too close to anything conductive.
Also, the zepp can show RF-in-the-shack problems since the feeder really isn't truly balanced... see Cebik, et,all. The balun and coax arrangement stands a better chance of being clean.
But, then, I don't know what the layout of you're installation is, so just a thought.

73, Stan

6267. Dipole vs End Fed Zepp for 20 meters

Yahoo group: ham-antennas (2008)
Date: 2008-10-13 01:46:54 UTC
From: Jonathan Helis KB5IAV
Topic: 6267 Message: 6267

My present antenna, a 60 foot half wave open loop in the attic, has only so so performance on 20 meters so I'm thinking of putting up another antenna for that band. My main interest right now is PSK31.

Since I live in close quarters and in a restricted community, I have to be stealthy about it so I'm going to mount it in my 19x20 foot wooden carport. I've determined ways I can put up either a dipole or an end fed zepp for 20 meters. Both antennas would have to be bent of course, but it could be done. I already have an antenna tuner(LDG Z11 Pro) and 2 different baluns, an LDG 4:1 and an MFJ 1:1/4:1 switchable balun.

The carport peak is around 15 feet off the ground, which is where most of the antenna(around 20 feet of it) will be, with the ends bent and sloping down a little.

I'm trying to determine which route would be the best way, since both antennas take up the same space. I'm trying to work all states and DX using PSK31 on 20 meters and need a better antenna to do this, so I'm trying to determine if the zepp or dipole would work better.

Also, if I go with the dipole, I'm wondering if I should feed it with coax or a balanced line like twinlead or ladder line, which I know I'll need for an end fed zepp.

If anyone has tried both an end fed zepp and a dipole, which would you go with?

Any insight is appreciated.

From: Joe
Topic: 6268 Message: 6268

Hello All,

I'm finally getting back on HF after a 15+ year lapse. And this time have a rig that can play on a band I have never been on 160 Meters.

I am looking forward to it for sure! but of course now looking for cheap, (fixed income) antenna, that I can try to make. A simpsle dipole of course is a possibility, I could indeed stretch one between some trees I have, but even then i doubt the efficiency would be any better than some sort of an optimized sub full sized abntenna because at the wends of the diploe may at best get 30 feet off the ground, so the center I probably could have my wife hang laundry on. so doubting it would get out very well,

soo looking for suggestions of what to try.

Low trees,, maybe max 30 feet, tall
no tower,

anyone?

Joe WB9SBD

I use the G5RV as an inverted V up 30 ft.

Also, Alpha Delta makes the DX-LB for 160, 80, 40 meters.

I've got a 260 foot fan dipole up just 30 feet in the center, with the ends up about 10 feet.There's also an 80 meter, 40 meter, and 17 meter set of wires, off the same feedpoint. Seems to work fairly well for me.

Thanks all so far that have replied so quickly!

it is encouraging to hear success stories about antennas that are at
such a horrid of a fraction of wavelength off the ground!

Thanks

With these low mounted antennas, you will be limited in what you can work, but you can also depend on teh DX station's setup to aid you. If he is a big gun on 160 or has verticals and beverages, he will probably hear you. That is what I rely on, the other guy. Example, I worked VP6DX Ducie Is. on 160 SSB and CW because of their antenna arrangements.

The inverted V arrangement gets you some omni directional capability, but maybe a high angle takeoff.

I do work in to some EU areas and Carribean also.
It will be challenging but fun.

I am using a sort of fan dipole. The top wires are a full sized 80 meter dipole with chokes of 100 turns on a 1.825" PVC form on the end and another 22 feet on each leg to make it a 160 meter shortened dipole. The SWR is below 3:1 from 1805 through 1875.

The next leg down is a full sized 40 meter dipole with chokes of 57 turns on PVC and 12 foot long extention legs to give me 75 meters. This plus the first legs give me full coverage on 3.5 to 3.990 with less than 3:1 for the whole band.

The third leg down is a full sized 30 meter dipole with chokes on the ends with 20 feet added to give me 60 meters with less than 2:1 on either band.

On 160 and 75/80 it is a cloud burner, but it is up only 38 ft in the center. 40 and 30 works well both day and night. I use something else on 20 and up, and don't want to confuse the issue.

Joe:

If you can, I would go with the dipole. Place the center in a tree and have the ends no higher than the center. The ends slightly below the center would be optimum. You will be surprised how well this will work on 160.

Another alternative would be a closed loop 500 ft total length fed with balanced line. It does not have to be perfectly square or round so it can use the trees. It will require a tuner capable of tuning to an antenna with balanced line on 160. This can be used on all bands.

A ? wave or ? wire fed against a ground system will also work. If you go this route let us know and we will give you more details about the location of the coax and the ground system.

Jonathan,

This site has a pretty good article on ladder line and building your own. Better than most store bought ! Let us know if you go this route.

Betreff: Re: [ham-antennas] 160 Antennas,

Joe:

If you can, I would go with the dipole. Place the center in a tree and have
the ends no higher than the center. The ends slightly below the center would
be optimum. You will be surprised how well this will work on 160.

Another alternative would be a closed loop 500 ft total length fed with
balanced line. It does not have to be perfectly square or round so it can
use the trees. It will require a tuner capable of tuning to an antenna with
balanced line on 160. This can be used on all bands.

A ¼ wave or ¾ wire fed against a ground system will also work. If you go
this route let us know and we will give you more details about the location
of the coax and the ground system.

Subject: [ham-antennas] 160 Antennas,

Hello All,

I'm finally getting back on HF after a 15+ year lapse. And this time
have a rig that can play on a band I have never been on 160 Meters.

I am looking forward to it for sure! but of course now looking for
cheap, (fixed income) antenna, that I can try to make. A simpsle
dipole of course is a possibility, I could indeed stretch one between
some trees I have, but even then i doubt the efficiency would be any

better than some sort of an optimized sub full sized abntenna because at the wends of the diploe may at best get 30 feet off the ground, so the center I probably could have my wife hang laundry on. so doubting it would get out very well,

soo looking for suggestions of what to try.

Low trees,, maybe max 30 feet, tall
no tower,

anyone?

Joe WB9SBD

If it's the same thing I ran into, it's a pain to find.

I have a nice OCF dipole (I know it's nice, because I made it!) that I can tune on 75 and 20 or 40 and 20, but not all 3. If I put three 14 inch diameter loops into the feedline in my shack, it tunes up for 40m. If I separate the loops, it tunes up for 75, but 40m goes to an SWR of 2.5:1. All the while, 20m remains unchanged.

I spent most of one day puzzling it out, but I have to admit, the cats enjoyed helping me play with the coax!

Good luck!

Mike, it looks from your write-up like you're using coax to feed the antenna, if so I suspect that you have RF on the cable's shield.
Under those circumstances, what's happening is that the feed line is acting as part of the antenna and is radiating some signal, that's why you can tune it in the shack the way you describe. Problem here is that your radio and tuner are part of the antenna as well.

A 1:1 current balun or coax choke up at the antenna end of the cable should correct the RF leakage problem, but you may wind up being disappointed by its not tuning any better, and possibly even worse. Add to that, the lost radiation from the shield may actually reduce the antenna's effectiveness in some situations.

As long as you're not interfering with your shack equipment or the stereo in the next room, it might be something you can live / work with.

One question comes to mind, though... do you have the cable grounded where it enters your house? Lightning is NOT someone you want to invite in for tea.

Ham radio... stuff to tinker with.

Have fun, but be safe!

Stan

> 73, Stan

Right after I posted my first message, I started thinking about putting up a dipole instead, so I posted that question to the list too.

One thing I've been thinking about is multiband operation for the bands 20, 17, 15, 12, and 10, so today I started thinking of perhaps a trap dipole. That could be fed with coax so I wouldn't have to deal with the hassles of twinlead, ladderline, etc. I know there are advantages and disadvantages to them, but I've never worked with one before and it might be fun to give it a shot.

Now I just need to find some good resources on constructing one.

6282. Under the Eves Loop

Yahoo group: ham-antennas (2008)
Date: 2008-10-14 07:08:47 UTC
From: Dennis
Topic: 6282 Message: 6282

I would like to try a loop antenna under the eves of the roof which would be out of the way, as far as visually, for my wife. The house is 75 feet in length and 25 feet in width. On each end of the house, west and east, is a small rising gable. The total length of the wire would be approx. 200 feet to 210 feet. I'm thinking of using 16 or 14 guage insulated wire. I haven't any experience in loop antennas but if the height above ground is abt 10 feet on the long sides and alittle higher on the gable ends would it be a good design to do a decent job on most of the bands? Thanks for your responses in advance.

Feed it with 450 ladderline and it will work pretty good, maybe even tune up on 75 with a good tuner. Any antenna is better than no antenna..73, Alan

Thanks, Stan, and yes. :) I do have it grounded and you're right about the coax - at least, that's what I came up with as well. Since it isn't a problem and I can "tune" it from inside the shack without using a tuner, I'm pretty content.

6285. 52-75 ohm broadband transformer

Yahoo group: ham-antennas (2008)
Date: 2008-10-14 14:32:11 UTC
From: Doug Chlan
Topic: 6285 Message: 6285

Hello All,
Found an interesting article in the 17th edition of the ARRL Antenna Handbook. a 52 - 75 ohm broadband transformer so that 75 ohm tv coax can be used. Does anybody know if a company makes these? (MFJ etc...) Any help appreciated.

Cheers!
Doug...

6286. Inverted - Inverted V

Yahoo group: ham-antennas (2008)
Date: 2008-10-14 15:17:06 UTC
From: Pete Mihnovets
Topic: 6286 Message: 6286

Ok, I am trying to understand why inverted V antennas have the feedpoint at the top.

Is it possible to change the configuration so that the feedpoint is at ground level with the to legs at the top.

Seems that your feedline would be shorter for very tall installations and grounding at the feedpoint easier.

Any thoughts???? I am sure I am not the first one to ask this question.

Pete,
Check the bottom of page 153 in Carr's book - inverted V changes radiation pattern, impedance and of course length for desired resonance as opposed to dipole - by changing the height above ground reference.

Regular V would probably do the same and would be nice to experiment with or just model it. I think the proximity of feed point to ground would have the most undesired effect - for comparison check the impedance and radiation patter of plain dipole versus height above ground.

It always puzzles me why some hams strive for tall towers knowing that after the antenna is above half wavelength above ground it develops multiple vertical lobes thus spreading the effective power.
The inverted V does just the opposite.

Here is the link

http://books.google.com/books?id=f3asJreno0YC&pg=PA144&AN>;lpg=PA144&dq=dipole+radiation++%22versus+height+%22&source=web&ots=068sccmFIM&sig=dEUkIqlr10DmeVvLAUXWLl1n3W4&hl=en&sa=X&oi=book_result&resnum=3&ct=result#PPA153,M1

Hi Doug,
Never mind about the slight mis-match introduced by using 75 ohm coax. If your is SWR 1:1 using 50 ohm coax,then it will be 1.5:1 using 75 ohm CATV line. Seeing that you are SWL, you don't need to worry about it at all. Of course, if you want, you could cut the 75 ohm cable in 1/2 wave multiples of your operating frequency.

The purists here may hurl radioese at me for suggesting that, but I have used 1/2 inch 75 ohm CATV hardline for years at VHF and what can I say? It works!

Have a look at
http://k5dwj.com/ham_hardline_more.htm
for supporting info. If you Google you will probably find lots more info.

If you REALLY want to use an adapter, MFJ makes one or you could build your own. Have a look at
http://www.repeater-builder.com/rbtip/matchingstubs.html
for info on that. I built 2 of these and I found it to be much more effort than it was worth.

Eric 9Z4CP.

Hi Eric,
Thanks for the reply. Yes I am SWL right now but I have written and passed the Basic Amateur Radio exam here in Canada and am just patiently waiting for my license. The 75 ohm coax is going to be used with my main HF antenna so I want to do this right. You say MFJ makes a transformer, do you happen to know the model # ?

Cheers!

There actually is a commercial antenna manufactured along those lines, but it isn't truly an inverted vee. It is sold as a broadband antenna. This antenna has a large ferrite bead at the feed point. It also runs a wire along the ground sort of like a radial. This radial is grounded. The far end of the wire radiator is terminated in a resistor.

The problem with these antenna is that pesky resistor. They absorb RF energy that isn't radiated.

The inverted vee is a fabulous antenna for general amateur work. It can be coaxially fed at the center, or fed with balanced feed such as window line and in this configuration works great on odd frequency multiples. It also can be off center fed, often at the 42% mark. This lets it work even harmonics, but not the odd multiples. So, an 80 meter version will work at 3.5, 7, 12 and 28 MHz, in theory. In practice, end effects play havoc on the upper bands. If you go with coaxial feed, then you will want a balun at the feed point. 1:1 works great if center fed, and 9:1 or 450 Ohms is acceptable on the OCF version. You can move the feed point around and make it "see" other impedance points, so a 4:1 wants a 200 ohm point. To do this, you really need to get yourself a copy of antenna modeling software.

6291. OCF Dipole

Yahoo group: ham-antennas (2008)
Date: 2008-10-15 01:30:03 UTC
From: Jonathan Helis KB5IAV
Topic: 6 Message: 6291

The latest idea I've brainstormed is an OCF dipole. I was thinking of building one for 20-10 meters, mainly due to space limitations and the need for stealth. I've caculated it would need to be around 34 feet long to load on 20 and I would need a 4:1 balun. I already have a preassembled length of coax to connect to it and a huge spool of wire I bought cheaply on Ebay over a year ago that wants to be made into antennas<grin>.

In my research, I've read about a no-tuner OCF that was 135 feet long and gave good SWR on most of the ham bands. Mine won't be this long, but I'm wondering if I would acehieve similar results. Has anyone else tried this?

It probably doesn't matter much, since I already have 2 tuners, a homebrew and an LDG Z-11 Pro autotuner.

I know I keep clogging up the list, but since my XYL's shortwave antenna was taken down during Gustav and she isn't interested in putting another one there, I want to make use of the space. I do alot of operating on weekend afternoons when 20 is open, alot of PSK31, and would like to be able to get some RF out of the house I'm having due to my other antenna being in the attic.

This list has been very helpful to me so far, and to others. Nice people here always willing to help with advice.

Thanks!

Some years ago, I played around with 75-ohm hard line and 50 ohm antennas. I tried all kinds of matching schemes. The loss in the matching sections particularly in the additional connectors was far greater than the loss caused by the ever so slight mismatch.

I concluded that the best way to match a 50 ohm antenna to 75 ohm line is to close your eyes and repeat after Me: "this is 50 ohm line". Then treat it as such.

Exactly you nailed it Walter

I have a friend now a sk who worked over 200 grids
on 144 mhz using left over cable tv 1/2 " hard line he
got for free, nothing fancy 180 watts single boomer.

He made his own adapter connectors with hardware
store plumbing brass fittings he did this with out a
machine shop just hand tools.

[snip]
close your eyes and repeat after Me: "this is 50 ohm line".
Then treat it as such

6294. 80 meter double bazooka from 75 ohm cable

Yahoo group: ham-antennas (2008)
Date: 2008-10-15 13:41:43 UTC
From: Bruce E. White
Topic: 6294 Message: 6294

I am interested in constructing a double bazooka from a length of Belden 9114 (75 ohm RG6) that I was given. Most plans call for 50 ohm coax. Does anyone have any experience with this type of cable as far as length,matching, etc. on this type of antenna.

73 and tnx

Topic: 6295 Message: 6295

Hi Everyone,

I'm glad to a member of this group. Antennas have always been of interest to me. Lots of unanswered questions revolve around them.

Beginning in 1957 I replaced Zepp antennas on C-121 aircraft. There two on each aircraft, each 67 feet long. I believe the C-54 antenna was the same length. I've not been able to learn the length of the antennas on fighters. Does anyone remember?

When I earned my novice that was my first antenna and the old Heath DX-20 tuned it like magic.

> iam thinking of putting a wire antenna outside for recieving hf

Hi Alan,

Besides the obvious of just wire being much cheaper there are many versions of the g5rv. I would try a long wire first as high as you can get it. If you were just looking to operate on one band , a dipole cut to that band is the best. If you have a random wire tuner you can make just about any wire resonate on any band. A g5rv is just a dipole that with a tuner is the best compromise to work on the hf bands.

Technically speaking , G5RV is dipole only on the band where the entire wire plus the matching ladder line stub is resonant at half wavelength - hence two poles - dipole.

6303. Using Hrdline

Yahoo group: ham-antennas (2008)
Date: 2008-10-16 23:27:56 UTC
From: Dave
Topic: 6303 Message: 6303

I'm about to string hardline between the antenna (up a 60' tower) and my transceiver. Total run is approximately 275'. My question is how to secure this stuff to the tower. I see micrtowave towers in the area with multiple hardline runs and wonder if there is an metal or pvc type clamp that attaches to the tower, and secures the hardline as well. I could use some heavy duty cable ties, but I'm concerned that the hardline is sufficiently heavy to make them ineffective. Suggestions will be much appreciated.

Thanks in advance

Dave

Check out “adell” clamps , used every day in aircraft and race cars for fuel lines , wire bundles and so on. I use then for even holding my RG8 type line.

Dave

I forgot to add they are available in all types of material , plastic , nylon , SS , mild steel , alum ,Ti. You can get the plain or with rubber , silicon or Teflon lining (padding). I have used duel sizes and put a larger size around a mast and then the smaller one around the coax thus requiring only one fastener. Check out my picture of a pass through the group pictured files in the Kd0zz folder and you will see them in use for a coax support just outside my pass-through.

6309. Optimum Yagi Height in a Valley ???

Yahoo group: ham-antennas (2008)
Date: 2008-10-17 02:24:40 UTC
From: ash_lee52
Topic: 6309 Message: 6309

I am pretty familiar with the effect of antenna height on a yagi. At about 1/4 wl high programs like EZNEC show a YAGI to be directional but with a very high angle of radiation. By 1/2 WL the angle of radiation comes way down, and by 3/4 WL its about as low as it gets... above that you get lots of weird lobes. My question is this... for the low antenna is the RF actually leaving the antenna at a higher angle, or is it that the portion which leaves at low angles gets lost into the ground, taking it out of the picture?

Why do I ask? I live in a valley with mountains up to about 20-degrees above my horizon to Europe. So does this mean that I would get better performance with a lower YAGI and a higher angle of radiation? My signals tend to get out pretty well, but I hear way fewer stations than I did in another QTH.

Has anybody experimented with mounting Yagis in a vertical configuration on a non-conductive mast? Some modeling I have done suggests that this might be optimum for me. I know that UHF yagis can be mounted vertically.

OM,
I have taken liberty to insert some comments into your message.
I am assuming you are talking about HF antenna.
And my favorite subject of ?tall towers? overkill.
I am not sure if your concerns are necessary, but they are certainly valid.
I have always looked at the issue of side lobes with increasing height of the antenna as " distributing total power into too many directions".
As pointed out by others, the "propagation Gods"?are on the other side of the equation and IMHO are playing the first fiddle.
You can do the?math for each vertical lobe propagation path to come up with theoretical model.
But in practice I would stay at ? wavelength height ? putting all the energy into the main lobe.
You will save some $ on tower sections!
As far as vertical polarization ? on HF is does not matter ? the ionosphere mangles the wave polarization anyway. Of course the ?energy cone? should look different due to changing height of the Yagi elements above the ground reference. Never actually modeled that and will try that soon.

Topic: 6294 Message: 6314

The impedence of the coax cable doesn't matter, just the velocity factor. Google "double bazooka" & you should find a few calculators that will allow you to enter the coax type or the velocity factor.
I use one on 40 Metres made from RG59 (because we use it at work & often have 20 Metre long off-cuts, lol)

Hi Scott!

I took a solo trip from Alabama up to Michigan and back last June on my Suzuki - best time I've ever had! Stayed off the highway for the entire trip and went through dozens of small towns. All I can say is what a country!! Then last October, a guy pulled out in front of me and ended my motorcycling days. Humbug.

I was a tail gunner on an IBM selectric for my entire AF career - Accounting and Finance.

Have a good SAFE trip around the lake!

I put 25,000 miles on two small to medium size motorcycles, all in the Dallas metropolitan area.
When I turned 55 I decided I'd tempted fate long enough and sold my Suzuki SP370. I miss the bikes, but the percentages are just too much against us, especially since we olduns run to slow reaction times. BTW, I'm 75 now. All that bike history was way before I got interested in Ham Antennas, I'm not sure my luck would have held if I'da been talking while riding(G).

6319. Mobile Antennas

Yahoo group: ham-antennas (2008)
Date: 2008-10-17 17:27:00 UTC
From: Scott Laughlin
Topic: 460 Message: 6319

Hi,

Playing around with 2m mobile antennas has kept me occupied for several years. Buying a magmount for the roof of a car pretty will does the job, but on motorcycles and bicycles it's a different story

I've modified an ancient magmount from which the magnet is lost and mounted it on the luggage rack of my CB-900. I grounded the coax to the motorcycle frame. The SWR reads lower if I use motorcycle battery power than another isolated power source. But I never seem to be able to achieve much better than about 1.25:1.

A half-wave (j-pole) fabricated from tv twin-lead seems to work better. But each antenna seems cranky in its own personal way (I've built a dozen of them). Some will offer a 1:1 SWR while others require monkeying around with a decoupling coil to achieve that result.

The big draw back with the j-pole is having to shove it inside a section of pvc. Though they've waved around behind me for thousands of miles they are distracting in the mirror.

I chat on 2m only while on the bicycle. APRS is my main mobile interest, using n7net-6 with a Radio Shack HandiScratchy and a TT-3. I've had 11 motorcycles in all, but the 900 is the only one I've made radio active.

Has anyone found the perfect solution?

For portable low band I usually haul a SM-20 to my place in New Mexico and use a pruned dipole cut for 14.060. It cuts down on the motorcycle load--no tuner and fewer batteries.

6320. Antenna Grounds

Yahoo group: ham-antennas (2008)
Date: 2008-10-17 20:31:38 UTC
From: kb3oyf
Topic: 6320 Message: 6320

I'm going to be installing several antenna at my QTH. After reading several sources, I am planning to ground each mast using #8 Al wire and a ground rod (NEC requirement). There would be a seperate ground rod for each antenna.

I am also going to place a lightning arrestor at the entry point to my house and connect them to a ground rod at the entry point.

My question is will this cause ground loops?

Is there a differt grounding configuration I should try?

Thanks in advance for your help.

6321. What To Use For Poles To Mount Antenna ?

Yahoo group: ham-antennas (2008)
Date: 2008-10-17 20:34:35 UTC
From: kd0fae
Topic: 6321 Message: 6321

I have a 40 ft long parallel dipole which I want to install next to my house and extending into the back yard. I would like to mount it about 23 ft above ground, which would put it about 5 ft above the highest point on the house.

What would make good poles for supporting the ends of the dipole? The trees on my lot are not anywhere near where I can string the dipole due to power lines. Since the poles will be rather near the ends of the dipole (1 foot or so), I would rather have non-conducting poles. I don't know where to get a wooden rod that would meet my needs. PVC pipe is too flexible.

Any suggestions welcome!

Bill,

This stuff is great. I use it and the same thing in aluminum. The aluminum is a little strong but with the little bit you are going to have sticking up in the air it shouldn't matter.

Your local utility company may have power poles that no longer fill their needs. You can usually buy them by the foot and the price is reasonable.

Getting them home at an affordable cost is another problem.

6326. 4:1 Balum Core Saturation on Windum producing RFI feedback when using 600 watts

Yahoo group: ham-antennas (2008)
Date: 2008-10-17 20:59:53 UTC
From: Pete Mihnovets
Topic: 6326 Message: 6326

I am trying to get my SB220 to load up on a Carolina Windom 135 feet long. 4:1 Balun @ 70 feet elevation suspended by Carolina Pines. My problem is that I can get an input match for a few minutes then the SWR wanders high. I suspect that this is due to the 400T iron powder core heating up.

My question is this caused by the design of the unbalanced antenna? Does any one use one in the group with an amplifier with success?

I have used a line Isolator at 22 feet from the balun plus and 6" air 1:1 balun to reduce the RF skin affect RFI feedback. This has helped but not solved the issue.

I have a LDG 11MP auto tuner that I use to get a 1:1 match on the input side of the Amplifier.

And I also have a MFG 269C 3Kw tuner getting a 1:1 match on the output (Windum) side. After a minute of transmitting at 600 wats the SWR on the input side goes high and the transceiver power reduces due to it's solid state final going into preservation mode.

Any thoughts would be appreciated.

From: vaclav sal
Topic: 6320 Message: 6327

I would venture to say that electromagnetic wave being related to plain current flow will "seek" the path of least resistance to the reference ground, therefore your height above ground will always be the direct distance to the edge of the cliff, not to the foot of the cliff.

We could speculate and ask when the dipole above ground becomes dipole in free space.
If free space is defined as infinite distance from reference it does not help in your case..

Topic: 6326 Message: 6329

Quick thoughts

Your input match at the amp should not be so far off that you need a tuner inline. Figure out that problem sooner than later.

Are you hearing any arcing? Isolate that and replace jumpers or connectors until that stops.

Jumpers and connectors that look and act fine at 100W will not always carry high power.

What type and power rating is your 4:1 at the feed point? You shouldn't need any further isolation than that either.

What type of coax are you using for jumpers and feed line? IMO the high power side should all be 213 sized if it isn't already.

Does this antenna behave properly on its own, direct fed from the rig at 100W?

A steel 20' top bar for chain link fencing, and a 6-10' closet wooden hanging
bar for clothes, secured with a hose clamp inside the steel pole,
makes a pretty rigid support abot 25-30' high. Fairly light weight,
and inexpensive.
purchase a little larger 4' pipe, and pound it into the ground for
easy taking out of
the 20' pipe and putting it back up.

Don't have exact answer, but some comments.
Your rig has 50 Ohm output impedance, the SB200 has 50 ohm input impedance.Why are you using tuner on the input of the amplifier ?

Your "Isolator" should be at the input of the balun (at the top of the feedline) to stop coax skin effect current and to keep the feed line from radiating. Placing it anywhere else does not fully choke the unbalancing current.

As far as supporting Carolina Windom with Carolina pines - that rocks! Hi Hi

Original Windom was designed to match high output impedance of tube amplifiers - hence feed line was not connected to the center of dipole.

Matching the OCF Carolina Windom to SB220, albeit 50 impedance, seems "long way around the barn".

I would add ladder line, move the balun to the input of it and use G5RV setup.

From: Scott Laughlin
Topic: 6326 Message: 6333

Lee,

I used to run into an occasional problem on aircraft way back when, but the shop had a megger for checking out that sort of problem--bad coax, bad connectors, or some other problem.

My personal problem came on gradual, and I couldn't nail it down, so I reduced my power. I'd worry the SWRs down to 1:1 and after a time it was reading 1:5 or greater. Sometimes it was a spike other times it was slow. I replaced jumpers and pruned a dipole that would work without the tuner. That's when I nailed it down as something inside the match box. The first thing I changed was the antenna input connector on the tuner the problem disappeared. That was two years ago and it's still gone.

You should keep a running log on what you've done and what happened. It's easy to loose your way.

6334. Tuner placement

Yahoo group: ham-antennas (2008)
Date: 2008-10-17 23:07:13 UTC
From: barbiekenw
Topic: 6334 Message: 6334

, October 17, 2008 3:42 PMFrom:

I have Steppir vertical I use on several band with a couple of elevated radials in an RV park.

SWR is about 1.8 or less on those freqs that correspond to the radials. I am adding a tuner to add some frequencies. I have in the coax line a LP filter and a balun to decouple the feed line. Currently the set up is: amplifier - LP Filter - decoupling balun - coax exiting shack to vertical.

I was thinking that maybe the LP filter or the decoupling balun might work better at lower SWR. So I could place the tuner between the amp and the LP filter,or between the LP filter and the balun, or between the balun and the feedline exiting the shack.

I have a feeling placement does not matter, but I wondered if anyone has other information.

Ken

6335. angle of descent for G5RV as an inverted V?

Yahoo group: ham-antennas (2008)
Date: 2008-10-17 23:23:28 UTC
From: hochman_97
Topic: 6335 Message: 6335

I have a G5RV-Jr antenna which I want to hang as an inverted V...
what is the max angle the horizontal segments can droop from perfectly
perpendicular to the feedline without degrading performance?

Thanks.

6336. Re: angle of descent for G5RV as an inverted V?

Yahoo group: ham-antennas (2008)
Date: 2008-10-17 23:42:31 UTC
From: Scott Laughlin
Topic: 6335 Message: 6336

I would try 45 degrees on each side of the apex.

I use a larger G5RV at my QTH which is pretty restricted. The Apex is up at 20 feet then down at 45 degrees for about 15 feet. Then the legs take a 45 and follow a wooden fence that hugs a swimming pool. It lacks a great deal from being an ideal situation, but it does well with QRPp. With .075 watts output I'm just shy of my 1,000-miles-per-watt certificate with that configuration.

The angle between the two legs should be kept close to 120 degrees
according to everything I've read. 45 degrees on each side would only be
90 degrees between the legs. I have a full size G5RV configured that way
with excellent results.
My 2 cents.

A steel 20' top bar for chain link fencing, and a 6-10' closet wooden hanging
bar for clothes, secured with a hose clamp inside the steel pole,
makes a pretty rigid support abot 25-30' high. Fairly light weight,
and inexpensive.
purchase a little larger 4' pipe, and pound it into the ground for
easy taking out of
the 20' pipe and putting it back up.

Pete,

I fought a similar problem with a G5RV. It turned out to be the RF connector on the tuner. It looked okay but it wasn't.

It's hard on radios.

When we first moved to Texas we rented a house where I wasn't sure what the neighbors would say about an antenna. So I laid a G5RV Jr. on it's side and hid it in a live oak tree. The apex was pretty sharp and pointed directly at 1 country. It worked and kept me on the air with five watts for a year. But it certainly had a back side.

Yes, the military portable masts work great. Be sure to get guy rings. At about 24 feet tall (4 foot sections) using fiberglass you should use a guy ring every 8 feet, plus at the top (that makes 3 rings). Be aware that these fiberglass poles will decay with exposure to the suns UV rays. You'll need to paint the poles if you want a permanent installation.

If you use aluminum you can go 3 sections per guy point. I didn't guy the top of my 40 foot aluminum mast and it's holding fine with just the inverted V wire antenna to steady it.

What great bluffs you have out there too Bill. Yet while you get the 'distance' I'm a'thinking (southern technical term)
that unless your 'view' to the horizon is what is gonna get ya.

Think of it this way, if all you needed for a great antenna was a hole to stretch the wire over, mine shafts
would be great spots.

Make sense?

I REALLY need to look at things before I hit send! haha

What I ment was, unless the ground is in fact 'ground' not just a valley floor of some chasm, your take off is gonna be blocked by earth.
Or at the least be very directional depending on which way the 'valley' is pointed.

Hence, the reasoning behind not just digging a hole for the extra height.

Works for big radio telescopes but not dipoles.

yes but this is very hard to explain trying to describe geographically my installation.

Everyone talks about getting their dipole as high as it can get to assist the SWR and radiation of signal.

I was wondering if the antenna sees the ground around it or sees basically nothing due to it height above the valley

If I understand correctly, you have a tall cliff, and you want to hang an antenna off the side of the cliff in order to make it appear as a high antenna, well above ground, using the cliff as a natural support.

Either that, or you want to erect a tower or string a wire between trees, and want to know how far away from the cliff it needs to be.

If the cliff were (say) 50 feet high, and you mounted the antenna 50 feet sideways away from the cliff, then it would see the ground 50 feet below it, but it would also see the cliff 50 feet to its side, which will definitely affect (skew or distort) its radiation pattern.

At less than 50 feet (i.e., the height of the antenna) from the cliff, the effect probably gets worse.

So part of the answer to your question depends on knowing just how much distortion in the radiation pattern from the cliff you can tolerate.

If you want it to behave like a textbook antenna above flat ground, it may need to be several times the longer of (a) the wavelength, and (b) the antenna's height, away from the cliff.

On the other hand, if it's a beam or yagi antenna aimed away from the cliff, maybe it could be a lot closer.

I'd be tempted to want to model this in one of the NEC derivatives or another antenna modeling program, one that is known to handle rocks and real earth ground, to investigate this problem.

So, I can't answer your question. Sorry.

Regards,
Andy

> Can anyone tell me how close to the edge of a mountain bluff a dipole
> installation needs to be in order for the antenna's electric formula to
> "see" the height above ground of the valley below.

If I understand correctly, you have a tall cliff, and you want to hang an antenna off the side of the cliff in order to make it appear as a high antenna, well above ground, using the cliff as a natural support.

Either that, or you want to erect a tower or string a wire between trees, and want to know how far away from the cliff it needs to be.

If the cliff were (say) 50 feet high, and you mounted the antenna 50 feet sideways away from the cliff, then it would see the ground 50 feet below it, but it would also see the cliff 50 feet to its side, which will definitely affect (skew or distort) its radiation pattern.

At less than 50 feet (i.e., the height of the antenna) from the cliff, the effect probably gets worse.

So part of the answer to your question depends on knowing just how much distortion in the radiation pattern from the cliff you can tolerate.

If you want it to behave like a textbook antenna above flat ground, it may need to be several times the longer of (a) the wavelength, and (b) the antenna's height, away from the cliff.

On the other hand, if it's a beam or yagi antenna aimed away from the cliff, maybe it could be a lot closer.

I'd be tempted to want to model this in one of the NEC derivatives or another antenna modeling program, one that is known to handle rocks and real earth ground, to investigate this problem.

So, I can't answer your question. Sorry.

Regards,
Andy

In the broadcast industry where the coax is 3, 4 and sometimes 6" in diameter the standard practice is to use stainless steel worm screw clamps, just like hose clamps. They can be had at companies like Andrews. Kind of expensive, but I've seen them last well over 10 years. They don't deteriorate because of UV radiation like plastic wire ties, they don't stretch like plastic ties and can handle high winds and ice loading.

If I am reading you right, the "ends" are the antenna ends, and the "poles" are the power company supports? If this is correct, then I would recommend you do anything that keeps you away from the power poles for safety reasons. Do whatever it takes to keep away from those power poles. Fold the antenna to make it fit in a smaller area, use loading coils to shorten the antenna, anything. I would rather call you sparky because you like CW than because it was what got you in the newspaper in the obituary section.

Here are some ideas. I built a couple of antenna using large 1 1/2" PVC pipe sections to wind a couple of 140uh coils. These take about 100 turns of #18 wire. Put these on the ends of 66' long dipoles. Add around 15 feet to the ends, and now you have an 160/80 meter dipole. Make the coils 60uh the legs 33' and the stubs about 10' and now you have 80/40 meters. See where I'm coming from? Reduce the lengths and get extra bands to boot.

Traps are another way to shorten an antenna to fit in a smaller length. Putting 10, 15, 20 and 30 meter traps in the correct places can make a 40 meter dipole fit where it normally wouldn't. Unadilla makes some great traps if you don't want to make your own. They have one model that makes a dipole fit in 60' of space.

What ever you do, don't tempt fate and mess around near the power lines.

The low pass filter should be after the amp to stop the radiation of spurious signals from all amplifying stages. The tuner should be between the filter and the antenna. The filter works best when terminated at the design impedance.

I would think it would be better to add the proper radials and not use a tuner at all if possible. The radials will increase the radiation efficiency, the tuner will add losses, not contributing to the radiation pattern but making heat in it's little box. If you need to, you can always use loading coils or even traps to make the radials work on more than one band. I know one ham that used a multi-band dipole to make his radials. Works fine for him.

Hope this helps.

Not very long at all -- the few I've seen were built into the vertical
stab.

Try 4" or even larger diameter PVC pipe -- it isn't very flexible at
all. I use a piece of 4" diameter with my Icom AH-4 mounted on the top
end of it and braced next to the end of the house. It's been up there
several years and works great.

I used a 30 foot telescoping mast with an 18" standoff at the top for my center support. I ripped a 10 foot 2x4 in half and hose clamped the 2"x2"x10 foot planks to metal T posts driven in to the ground for my end supports. They put the ends of my dipole at about 12 feet high. There are lengths of nylon cord separating the ends of the dipole and the wood posts. Seems to work OK.

Hi Earl,

Great to see you here.

I know the antennas grew smaller as the aircraft exceeded speeds too fast for wire antennas. Our Super Connies were approaching that speed. I restrung a bunch of them, especially the #2 antenna that went to the outside vert stab. It always went first. The C-54, C-124 and others were a straight shot in the early '50s.

The fighters of that era had already surpassed those speeds and I was never given the opportunity to work on a P-51 or a P-38.

My first transmitter was a rockbound Heath DX-20. I could tune the hf band (except 160) with a 67 foot Zepp wire with no tuner.

Weren't you and I who both made our first SKCC contact?

Dave,

You might check out the unistrut system.

http://www.unistrut.com/

I've used there channel and simple two part clamps for many antenna applications. Once you have a channel mounted to the tower side (horizontally at several levels on the tower), it's easy to clamp and rearange any thing runnig up the side of your tower (crank-up towers might present some limitations!). You can find the channel and clamps at Lowes, Home Depot etc in the electical section. Last time I bought clamps, the best price was from McMaster-Carr. Once you start using this stuff, you'll find all kinds of Ham Radio applications.

Boy that's the truth -- the 121/Connie was one fast plane for it's time, and for recips, too! I saw one on the ramp just a couple of weeks ago, BTW -- Salina, Ks I think it was.

<snip>
> The fighters of that era had already surpassed those speeds and I was

Most of the fighters I was around didn't have HF, but occasionally I would read the T.O. or talk to others, or even wander through their hanger and take a look. Seems like they had a pretty hefty auto-coupler at the base of the vertical stab and I think they used an HF similar to what the C-141 used -- and on the C-141, it would tune that spike almost anywhere from way below 40 meters all the way up to 30 MHz, maybe more. I only got to use it once, on a transcontinental flight, and I got the pilot a phone patch to his brother, via the Maritime Mobile Service Net. The whole aircrew was sure impressed, and once the phone patch was completed, I had an instant pileup to work!

I'm not sure -- that sounds familiar, but I'm not finding your call in DXKeeper -- so I'm just not sure.

6361. efficient, easy to build or install dipole wire antenna that will cover 160-10

Yahoo group: ham-antennas (2008)
Date: 2008-10-20 00:56:45 UTC
From: Dennis G. Peterson
Topic: 6361 Message: 6361

Hello every, I am new to this group. I need some expertise from someone who has built and used efficiently a dipole antenna.

I want to put up a dipole that will cover 160 meters thru 10 meters. I have limited space but do have two pine trees about 120 feet apart and a elm or maple that is off set but kind of centered between the pine trees. In the back yard, the yard is short but the trees and woods go back about a block or even more.

The problem I am having is getting the antenna up at least 30 feet or more. Prostate cancer and other medical issues are preventing me from throwing like I used to. I seem to be able to only throw about 20 feet up if that much.

I was absent from ham radio for almost 3 years and am just getting back on. My station consists of an ICOM 735 transceiver, an Astron RS20A power supply, an MFJ 949E Delux Versa Tuner II. I will be running only 100 watts.

MY FAVORITE BAND IS 160 METERS. I want to be able to use all bands and I have been looking at several manufactured antennas, but I have limited financial resources due to the medical issues.

I have enough 14 gauge insulated stranded wire and nylon cord to pull the antenna up and tie it off. I don't seem to be able to locate the 300 ohm twin lead as no one locally has heard of it. I think I would also need a balun at the bottom of the 300 ohm twin lead. Need to know who makes the best and most efficient one. I already have the coax cable from inside the shack to outside which is RG8x. However if I need to run the twin lead directly to the tuner I will have to modify somewhat which isn't a problem.

Sorry for the lengthy post

In Advance Thank You and 73s

Dennis , don□t worry you are not the only one who can□t throw very well any more , two back operations , fused vertebras, and then my cancer messed up my neck and shoulder when they took parts and muscle out , but enough about the fun things let□s get back to antennas. I use a fishing pole , throw it over the tree then , pull a string back through, then hoist up one end of the antenna. I also made some tilt over poles that make a good supports. There are pictures in the kd0zz group picture file. If a cripple like me can make them any one can do it

Rich , KDØZZ

Dennis , don't worry you are not the only one who can't throw very well any more , two back operations , fused vertebras, and then my cancer messed up my neck and shoulder when they took parts and muscle out , but enough about the fun things let's get back to antennas. I use a fishing pole , throw it over the tree then , pull a string back through, then hoist up one end of the antenna. I also made some tilt over poles that make a good supports. There are pictures in the kd0zz group picture file. If a cripple like me can make them any one can do it

Subject: [ham-antennas] efficient, easy to build or install dipole wire antenna that will cover 160-10

Hello every, I am new to this group. I need some expertise from someone who has built and used efficiently a dipole antenna.

I want to put up a dipole that will cover 160 meters thru 10 meters. I have limited space but do have two pine trees about 120 feet apart and a elm or maple that is off set but kind of centered between the pine trees. In the back yard, the yard is short but the trees and woods go back about a block or even more.

The problem I am having is getting the antenna up at least 30 feet or more. Prostate cancer and other medical issues are preventing me from throwing like I used to. I seem to be able to only throw about 20 feet up if that much.

I was absent from ham radio for almost 3 years and am just getting back on. My station consists of an ICOM 735 transceiver, an Astron RS20A power supply, an MFJ 949E Delux Versa Tuner II. I will be running only 100 watts.

MY FAVORITE BAND IS 160 METERS. I want to be able to use all bands and I have been looking at several manufactured antennas, but I have limited financial resources due to the medical issues.

I have enough 14 gauge insulated stranded wire and nylon cord to pull the antenna up and tie it off. I don't seem to be able to locate the 300 ohm twin lead as no one locally has heard of it. I think I would also need a balun at the bottom of the 300 ohm twin lead. Need to know who makes the best and most efficient one. I already have the coax cable from inside the shack to outside which is RG8x. However if I need to run the twin lead directly to the tuner I will have to modify somewhat which isn't a problem.

Sorry for the lengthy post

In Advance Thank You and 73s

Dennis,

I used a 25 pound bow, a target arrow and 25 pound test fishing line to get over the trees that were about 50 feet up. I used the fishing line to pull up mason line and the mason line to pull up 1/8 inch nylon rope. I pulled up 3/8 rope with that. Takes about 15 minutes total to get to the 1/8 inch nylon rope.

BTW, I drilled a small hole at the back of the arrow. Also, lay the fishing line spool flat and let the line spook off the side. If you let the spool spin it will put too much drag on the line and arrow.

Good Luck

6367. G5RV-Jr ...how badly can performance be degraded if setup wrong?

Yahoo group: ham-antennas (2008)
Date: 2008-10-20 06:37:10 UTC
From: hochman_97
Topic: 6367 Message: 6367

I have a G5RV-Jr antenna and due to restrictions in my backyard I'm having some trouble getting the most from it. The problems I have are that the radials slope down at sharp angles (i.e. greater than the optimal 120 deg that I've read about). I have the center feed of the antenna up about 30' but I've noticed I typically get contacts from stations which are a few hundred miles away, but anything further is fairly garbled (typically on 20M/40M).
What I'm wondering is if it's possible to improve the performance of the antenna, or if it's very sensitive to height/radial angle, etc. I have heard good things about them in general, but I know some people have them up much higher than I do. I'm also considering switching to a vertical to see if that improves my situation.

Dennis,

300 ohm TV twin lead is almost impossible to find these days. Last fall I put up a 160 meter dipole fed with 450 ohm ladder line 50 feet high in the trees. Each leg is 130 feet. With my tuner I can work 160 thru 10. Because of available trees I was only able to put the antenna up in an "L" shape instead of a straight dipole. Last winter I worked 65 countries on 160 meters with that setup. In my case the ladder line feeds directly to my tuner, but a friend put up a similar antenna in which the ladder line transitioned to coax thru a 9:1 balun with good results. You can get ladder line from The Wireman. If you can't get 130 feet on each leg then put up as much as you can as high as you can and use that tuner to match it. I went to Walmart and bought a slingshot and some 1 ounce fishing weights to hang the wires. If all else fails, You can always ask the local ham club for help installing that antenna. Most of them would be glad to help.

6370. inexpensive, safe way (for radio) to check optimal SWR on a band?

Yahoo group: ham-antennas (2008)
Date: 2008-10-20 15:43:24 UTC
From: hochman_97
Topic: 6370 Message: 6370

So, from what I understand (and sorry if this is a "beginner" question there is usually an optimal freq range within a band where the SWR of the antenna is lowest. Short of connecting the antenna directly to the radio (and possibly damaging the radio) is there an inexpensive way to tell where this range is for a particular antenna/setup? I know that an antenna tuner will always try to minimize the SWR the radio sees for the antenna, but this doesn't necessarily mean that the signal beyond the tuner sees an optimal antenna SWR. I know the indirect way is just to see who can be contacted, what the signal reports are on a particular freq, but I was wondering if there's another (possibly not too expensive) way? I'd imagine you could buy a fairly expensive antenna analyzer, but short of this is there a way to do this? Thanks.

How about a good old fashion SWR meter? Just reduce the power of the transmitter.

Most modern radios have built in protection from high SWR and will automatically reduce
the power if the SWR is too high.

I admit I just passed my Tech exam and am waiting for my call sign but that doesn't stop my from learning and building and hence this letter/question.

When building an antenna what is the difference between using brass and copper? Both are great conductors, both are used in antennas and both take solder well and resonate equal as far as I can find in my limited reading...

HOW FAR off in left field am I? The antennas will be 95% indoors 2, and 10 meter units.

Paul , you will always get the □audio purists□ type people who say it has to be gold or silver plated. In the real word the only thing to you need to consider is if the antenna is going to be outdoors and in bad weather then you need to make sure you don□t get two dissimilar metals in contact and get corrosion in the joints. Brass and copper or a mix of both will work. They both solder very well. My j-pole is made out of galvanized steel because of the price of copper pipe. I have another with a stainless steel whip as the top element. The people on the receiving radio could not tell the difference. Most commercial 2m ¼ & 5/8 wave mag mounts are stainless steel because it holds up well and takes a nice heat-treat so if hit it will spring back. Copper wire or brass rod would conduct a little better but not hold up in use they would bend and look like a twisted coat hanger. Look at a ¼ wave vert made from a std coax fitting and some wire at my picture file with this group under Kd0zz. Any questions???? , feel free to ask what ever.

I would start with a cheap ☐CB☐ type SWR meter , I have a Swan Brand and a Radio Shack one the work for me with a range of 3Mhz to 150 Mhz. You can reduce power , check the antenna at several spots in the band and you can tell right where the sweet spot is and adjust if needed.

Paul , I will make another statement and I am sure some □experts□ will say I am wrong but you can solder almost any metal when you are making your antenna. They only thing I had a problem with was titanium rod. Try to used lead and/or silver based solder and a flux for stainless if you are going to try SS. The only secret is to wash it after to remove the excess flux. You can stop by your local welding shop and they will sell you a couple □heli-arc□ rods for next to nothing , ask for rods to weld 17-7. The come in 1/8 ,3/32 , 1/16 and 1/32 dia and are 36□ in length. The regular 321 316 type rods are soft and bend easy. 17-7 or even 17-4 rods have a good spring rate in the stock form so heat treat is not needed.

An antenna analyzer is basically a high tech grid dip meter. Grid dip meters are inexpensive (a lot of old time hams will give you one if you'll use it) and they're a great learning tool since you can find the resonant point on any circuit in just a few minutes. You can also use it to find the value of unknown inductors and capacitors. Look it up online or contact one of your local, old time hams.

I am planning on purchasing a multi-band vertical antenna within the next week or so, but I want to make sure that I place it in a location that is safe. I've read that ~20' from buildings is a good rule of thumb. Is that an absolute minimum? I'll probably be running no more than 100W/SSB on the HF bands....just wondering how far away people need to be from the antenna to avoid getting too much RF. I know there are docs someplace on estimating this, but I'm not sure where to look yet. Thanks.

Subject: [ham-antennas] efficient, easy to build or install dipole wire antenna that will cover 160-10

Hello every, I am new to this group. I need some expertise from someone who has built and used efficiently a dipole antenna.

I want to put up a dipole that will cover 160 meters thru 10 meters. I have limited space but do have two pine trees about 120 feet apart and a elm or maple that is off set but kind of centered between the pine trees. In the back yard, the yard is short but the trees and woods go back about a block or even more.

The problem I am having is getting the antenna up at least 30 feet or more. Prostate cancer and other medical issues are preventing me from throwing like I used to. I seem to be able to only throw about 20 feet up if that much.

I was absent from ham radio for almost 3 years and am just getting back on. My station consists of an ICOM 735 transceiver, an Astron RS20A power supply, an MFJ 949E Delux Versa Tuner II. I will be running only 100 watts.

MY FAVORITE BAND IS 160 METERS. I want to be able to use all bands and I have been looking at several manufactured antennas, but I have limited financial resources due to the medical issues.

I have enough 14 gauge insulated stranded wire and nylon cord to pull the antenna up and tie it off. I don't seem to be able to locate the 300 ohm twin lead as no one locally has heard of it. I think I would also need a balun at the bottom of the 300 ohm twin lead. Need to know who makes the best and most efficient one. I already have the

coax cable from inside the shack to outside which is RG8x. However if I need to run the twin lead directly to the tuner I will have to modify somewhat which isn't a problem.

Sorry for the lengthy post

In Advance Thank You and 73s
de K0CKDennis

I can provide a photo of the limited space and would send the same if you correspond to my email address of dennisissure@...

I built one of these this year and took it to field day with the local club and it was a great hit we was able to get our dipoles up around 50 to 60 ft with ease.

Callum,
Just curious - what kind of trees do you have in your back yard?
?
My experience with following trees - in random order:
Hemlock - the line should?be close to trunk, line in branches can get stuck in pitch.
Western cedar - no matter where the line is (next to the trunk best) it will slide down with ease.
Cottonwood - use only when all the leaves are gone (...and the sky is gray). This tree eats the line with leaves pitch! Also if the?lane is left few years it will grow in! Branches break with ease and loud noise.
Texas oaks - most cooperative but the width of the crown is deceiving. The antenna ends up in the branches (Filed Day experience) - measure twice and cut once!
Alder - best to use in winter, too many little branches. Line grows in very early.
?
I found that combining cheap child?s bow with wooden arrows "harpoon" style is more accurate than sling shot. I use fishing pole stuck in the ground?next to me or helper holding it.
No additional or special hardware is required!
?
The brightly painted (easy to find when they get lost!) wooden arrows are weighted on the tip with 2-inch carriage bolt to get them down over the tree. Metal arrows are better, more expensive and?do not pick moisture.
?
My process is usually three steps - I shoot light fishing line first (10 pound or less), than this line pulls heavier fishing line over and the heavy line pulls?the real antenna support.
I use black Dacron rope (I think 200 pounds pull strength) - it may be more expensive but more common than real parachute line. It is absolutely weather resistant - I had my loop up for over 15 years in rainy Washington whiteout any problems.
?
My most memorable event - Field Day in public park where we installed 80 meter dipole over 150 foot hemlocks in less than half an hour. We?I had plenty of Scouts helping to pull 1/4 inch yellow poly ropes.
We got lots of looks and comments using fishing pole in vertical direction "Indian style". (Politically incorrect but still used in folklore and government!)
?
The only drawback is that you have to balance the first line strength with the power required to get the line over the tree and sometime the line breaks and than it is ? heads up!!!? to all present!
Loose arrow comes down with vengeance!
?
?
?

Greetings to one and all...

Hello I'm Ken K6KAW / AG. I just passed my general at the ARRL Pacific Div convention on Sat 10-18.
The rig I used to make my first 3 contacts was a borrowed 817 with a Super Antenna MP-1. I just love the radio.

I live in an apartment so the antenna need to be fairly small but still effective. I've been thinking about the S/A MP-2.

What better way to hone my skills than QRP!

6385. Vertical Yagi for HF ?

Yahoo group: ham-antennas (2008)
Date: 2008-10-21 17:04:48 UTC
From: ash_lee52
Topic: 6385 Message: 6385

Does anyone have experience using a HF Yagi in a vertical position, rather than as the traditional horizontal. I can't elevate a yagi much but modeling shows I'd get pretty decent angles of radiation using a low vertical orientation with a non conductive mast. I know vertical dipoles can work well... this seems to be a version of that with a bit more directional gain. A vertical dipole actually likes being close to the ground.

Ashton,
The issues will be if you usE a yagi vertically, this is assuming its on a 50-100 foot tower and your just turning it
on it axis then you will effectively have a vertical with no ground radials.
Unless your tower has a wide field of copper wire runs.

Yes, HF likes verticals and there is MUCH debate about what is better so we aint going there.
Yet, with interference from the tower and lack of ground plane (radials) a yagi on it side is not
going to give you what your looking for.

A vertical need to be close to the ground, abet on top of it with a large radial ground plane to work,
or it becomes a 'cloud warmer', good for 300-500 miles.
A above ground vertical, what your thinking of need tunes redials to work or back to be a cloud warmer.

Remember, as you get lower and lower in the 'AM DIAL', bigger and better antennas start to look like the AM stations
you drive past in the country. Big and tall with a field FILLED with copper wire.

Now of course if money is no problem, then there is a Japanese station that has a full size 80M beam you should
look at. He shunt feeds the boom for 160M. Yes, it is huge!

Hope this helps.

A low vertical dipole doesn't need radials, so why would a low vertical yagi?

EZNEC predicts a low vertical yagi (like 5 feet off the ground for the lowest part) should work pretty well.

Now that wouldn't be any fun at all! I like to plant those little insulators and watch the coax spring forth, finally growing tall enough to flower into bouquets of 1/2 wavedipoles and 1/4 wave verticals, trimmed with abundant j-poles and yagis....

A low (5') vertical dipole on HF will not give you any performance.

As far as a high (5') vertical you will not have much take off angle, in fact none.

They sell 'no radial verticals' all day long, but do you see any big contest stations using them?

Do your test and see for yourself, that is the only way you will be convinced.

You should realize though, EZNEC is theoretical and free space. So in practice your mileage may vary.

Hi, I built a 2m vertical Yagi by converting an FM antenna. According to my modeling in EZNEC, I get pretty much the same radiation pattern vertical or horizontal, but with a little less gain in the vertical orientation.

Want to trade EZNEC files so we can compare them?

Actually a lot of DX and Contest stations use low vertical dipoles. Remember "Team Vertical"?

I have over 150 countries confirmed within the last 2 years primarily using various vertical dipoles.

People generally find that the Sigma antennas (Force 12) the TW-Antennas (see reviews for TW2010 in the portable antenna area of eham.com) and the Par End-Fedz all work very well as low vertical dipoles.

I did put a small Mosley yagi up vertically this afternoon... I'll test it in CQWW, but the first contact is from Western Colorado to the Azores. And it has a 1-2 s-unit advantage over a half square and 2 different Buckmaster OCFs (set at different angles becasue this antenna has lots of lobes) on receive.

6397. RE: [ham-antennas] Vertical Yagi for HF ?

Yahoo group: ham-antennas (2008)
Date: 2008-10-21 21:51:10 UTC
From: Joe Ivey
Topic: 6385 Message: 6397

Lee,

When you use a yagi antenna, one side IS the radial and the other is the driven side. When you use a vertical ground mounted the ground and/or radials becomes the other half of the antenna. As for contesting, DXing and DXpeditions there are a lot of verticals use. I have worked many DX countries on a Butternut HF-6 with 4 25 ft. radials. So they do work.

Joe, W4JSI

Subject: Re: [ham-antennas] Vertical Yagi for HF ?

Ashton,
The issues will be if you usE a yagi vertically, this is assuming its on a 50-100 foot tower and your just turning it
on it axis then you will effectively have a vertical with no ground radials. Unless your tower has a wide field of copper wire runs.

Yes, HF likes verticals and there is MUCH debate about what is better so we aint going there.
Yet, with interference from the tower and lack of ground plane (radials) a yagi on it side is not
going to give you what your looking for.

A vertical need to be close to the ground, abet on top of it with a large radial ground plane to work,
or it becomes a 'cloud warmer', good for 300-500 miles.
A above ground vertical, what your thinking of need tunes redials to work or back to be a cloud warmer.

Remember, as you get lower and lower in the 'AM DIAL', bigger and better antennas start to look like the AM stations
you drive past in the country. Big and tall with a field FILLED with copper wire.

Now of course if money is no problem, then there is a Japanese station that has a full size 80M beam you should
look at. He shunt feeds the boom for 160M. Yes, it is huge!

Hope this helps.

73,
Lee

Subject: [ham-antennas] Vertical Yagi for HF ?

Does anyone have experience using a HF Yagi in a vertical position, rather than as the traditional horizontal. I can't elevate a yagi much but modeling shows I'd get pretty decent angles of radiation using a low vertical orientation with a non conductive mast. I know vertical dipoles can work well... this seems to be a version of that with a bit more directional gain. A vertical dipole actually likes being close to the ground.

how wrong you are,

that have polarity just as much as any other transmitted signal, it's
just after passing through and off the ionosphere they can be any
polarity when coming back down.

Phil,

You have the right balun according to Buxcom. I tried on here with 100 watts and completely wiped out every tv in the house.

The antenna is know also by a windom and that is one thing bad about it, tvi. You may want to try some ferret beads on the coax at the balun.

How far is either end of that wire from your operating position? It wouldn't be the fault of an efficient antenna radiating a kilowatt to interfere with your house if it was anywhere close to it.

You need both a 4:1 and a 1:1. For the 1:1 you can use a toroid balun, beads over the coax, or an ugly balun. In any case, you need the 1:1 to get rid of the RF in the shack and the 4:1 to convert the impedance from 300-75 (or 200-50).

Hi Phil, as Mike mentioned you do need both. I made an OCF and although I didn't get any tvi that I noticed, I was setting off the CO monitor in the house when tx'ing 100w ssb. I opted for the "ugly balun", I coiled the last 10ft of the coax rope fashion and then connected to the 4:1 balun. I've read that the choke is better if you lay the wire side by side on a round form, but this worked for me, no further problems.

Antenna polarization is just as important on HF as on VHF/UHF.

Most of the QSB experienced on HF is caused by the "Faraday Rotation" where the polarization of the signal is rotated when it passes through the ionosphere. As the amount of rotation changes, the signal lever rises and falls.

Paul,

I think you're wrong. That's why hf flat top dipoles and verticals
are interchangable. Try horizontal polarization with a vhf and watch
the signals disappear.

While it doesn't prove anything, my little experiment with a Mosley Mini 32 on its side (vertically oriented) with the lower elements about 3 feet off the ground has gotten me to the Azores and Japan on my first two attempts at DX... and this is from the bottom af a fairly steep mountain valley in Western Colorado.

Of importance, I am using a mast of fibreglass sections since I think a conductive mast would be an issue. I know I should lead the feedline away from the plane of the antenna, but I haven't yet been doing this.

The benefits of this set up are I believe the antenna will provide a low angle takeoff without needing to be on a high tower, and there is much less twisting moment in the wind etc so a very small unguyed mast seems adequate. Finally its a lot less visible, which is the primary motivation.

I know people successfully use vertical moxons... this is really just a derivation of that concept.

My OCF is 20 or so from my shack on one end too and above 40m I have RF issues. It's not my antenna, cabling, or feedpoint, it is the RF my antenna is radiating.

Save yourself a lot of trouble and simply re-orient the antenna.

Mine is where it is because it was a quickie repair job. When it was oriented parallel and much (>50 feet) farther away, no issues.

You are getting suggestions that will waste your time and money as they are fixes for things much less likely to be your problem.

A carolina windom shouldn't need another balun at all unless something else is wrong.

I think success while one person is making contacts while other folks watch and wonder is the location. For lack of something better I've wondered about "Hot Spots," better soil.

I've done some portable qrp and in spite of hanging the antenna in the same situation the results were always different with each location.

A late friend, kc7hcw (sk), used a homebrew 19 inch vertical for vhf when we were both technicians. He made contacts on simplex I could only dream about.

Scott,

There are several thing that come into play here.

1. Most VHF/UHF FM is vertical.

2. The terrain comes into play. Usually line of sight + 10%

3. Amount of power of the transmitting.

4. The height of both antennas.

5. A lot of mobile communications are done mobile. Vertical antennas are easier to mount that horizontal one.

For VHF/UHF DX most use horizontal. In this case they are getting signals bounced from the E layer. Then the signals act much like HF bounced off the F layers. The E layer come in around June and last until around August. (Here in North America)

I built and used one several years ago, but only as a listening antenna - I wasn't yet licensed. It did a GREAT job. I understand, however, that they aren't very good at transmitting, but I have no experience with that.

With all due respect, and I know each configuration has its own characteristics, but I think coiling up some coax into an ugly balun is easier to try than finding a new instalation for the antenna. My shack is on the second floor, about 15ft below and 10ft east of the feedpoint. If what I experienced was rf from the antenna, I doubt it would have disappeared by adding the choke, which I did at the suggestion of some experienced hams. If I understand it right, this type of antenna is prone to feedline radiation. The "Carolina Windom" version actually uses a portion of the coax shield for radiation, with a choke installed about 22ft down from the feedpoint, IIRC. I mean no disrespect, I just think that an ugly balun would be an easy thing to try before moving the antenna.

T2FDs are one subject about which you will hear a lot of conflicting information. Some like them; others say they are as bad as dummy loads.

Not that it is necessarily meaningful, but I will note that the FEMA seems to like them; I'm pretty sure they use them even at their fixed locations where they could put up something "better" (though they often have large collections of antennas in addition to the T2FDs). They have the advantage of not requiring matching to get reasonable performance (i.e., SWR of 2:1 or maybe 3:1 or better) over a very wide range of non-harmonically related frequencies. I *think* that the signal loss when transmitting may not be as great as some would lead you to believe; except perhaps at the bottom octave or so where losses do increase significantly.

Mr. L. B. Cebik (www.cebik.com) has a page about T2FDs, which is some of the only analytical data I recall seeing about them on the web. I don't remember it being very complete, though.

Radio amateurs have the advantage of HF frequency bands that are harmonically related, making it easier to construct multi-band antennas without the losses of T2FDs or other antennas with resistive loads in them.

Andy

We used the T2FD in the military very often. The good news is that they are flat across a very wide bandwidth. The bad news is that they are air-cooled dummy loads. At ONE frequency only the antenna is balanced and the Resistor (yes resistor - that is why they call them Terminated) absorbs very little energy and on all other frequencies it dissipates MOST of the energy you put into it. I never thought I would say this but you would be far better off with a Fan Dipole.

Hmm, that doesn't sound too promising. However, can't the resistor be tuned based on the freq/band you want to operate on? I would imagine it wouldn't be too difficult to arrange a setup where the resistor could be in a socket and quickly swapped out for another. Maybe not...just kinda thinking aloud on this one.

Thanks.

been done. I was just walking around at lunchtime wondering if anyone has every used helium balloons (or something similar) to temporarily lift up a dipole for better performance. I thought it was probably a crazy/impractical idea, but my quick search of the internet seems to have picked up some similar sorts of references (i.e. for instance, one case where a repeater was carried aloft with such an arrangement). Not that I recommend trying it, but I'd be interested in finding out if anyone knows of any cases were this was attempted.

Nope - It is the antenna which operates on one frequency better than others. The resistor provides the constant load when the antenna is not resonant***.

***Disclaimer - The antenna is never really resonant - The length of the elements dictate on which frequencies the antenna is most efficient - I say "frequencies" because you can get two or more if they are multiples of each other such as 40M & 15M.

I'm sure it's been done, going back at least as far as WWII, and probably a lot earlier.

There's a bunch of ham radio operators who use kite-lifted HF antennas. One of them who does this periodically is Dave Hatch N9ZRT, moderator of the Live-Wire Yahoogroup (http://groups.yahoo.com/group/Live-Wire/).

hochman_97

By all accounts, T2FDs are extremely good for receiving, but not so good for transmitted signal.

A full size T2FD is around 100 ' + , and as I understand it, are the best performers.

Angle of tilt is apparently critical, otherwise it's just another bit of wire in the air - not a T2FD.

If I remember correctly, no less than 40 degrees is about right.

Google T2FD for more info

(now putting on flack jacket, 'cos I expect to get shot down // flamed by the pros and cons alike !)

I always wondered if anyone had tried switching the terminating resistor out for tx, and back in for rx.
Because it does reduce the noise on rx, and must (surely) dissipate power on tx.
If so did it make a difference ?
Just curious.
ps
Agree about fan dipole being better, although I take it you're not to fond of them.
Why ?

We never switched the resistor in or out. It was a "fixed - take it out of the canvas bag and put it up antenna" - They do work but not as well as a resonant dipole at the same height. The dipole however is a "one frequency" antenna and not what the plans called for.

As far as Fan Dipoles go they also work fine but I have always had a heck of time tuning one. If I get it to work on one band the others go to he#&. I like separate antennas for separate bands but not many have the real estate that I do to hang them far enough to not effect one an other. My preference for Multi-Band Dipoles is a trapped item. You lose some in the traps but not much if it is a good trap. I have a 160/80/40M hung from my tower (not really high enough) that does well close in (NVIS) but stinks for DX..

Clint - W5CPT

Many tnx for quick reply, CLINT, maybe someday I'll try it and see, although fitting a full size

T2FD into my garden would be - interesting - to say the least. I call my full size 80m dipole

a ' double z ' because it winds back and forward, over the garden, so much, and my

inverted L goes round three sides of my drying green, but gives me 160m to 6m using

the internal tuner on ft 920. It's a Practical Wireless design from a few years back.

(Feb 2004, and Jan 2005) REAL ESTATE - I wish !

The reason I asked abt the fan dipole is that I have a 40m, 20m, 15m, and 10m multiband,

single feed, fan dipole in the attic, (again, they're wound round to fit in) and it works very well,

despite the proximity of cold water tanks, 2m, 4m and 70 cms aerials etc.

Maybe just lucky, I guess.

Although I did have one guy, from the local radio club, standing out in the garden

shaking his head and saying "That shouldn't work ! " Part of the fun, I suppose.

Anyway, tnx for the info.

Actually Paul and Scott are both correct.

In line of sight communication Polarization of the transmit and receive antenna need to match as there is nothing causing polarization shift. If you cross polarize you should in theory have infinite loss; however, in reality you only see about 28db. Since most VHF/UHF communication is line of sight you will run into this cross polarization issue and the signal will drop as Scott stated.

Now when you bounce off the ionosphere there is a polarization rotation as Paul stated and it varies with time. This is why sometimes a horizontal antenna is better at times and a Vertical is better at times for receiving the same signal. (Note this is assuming a dipole for the horizontal which has as much or more gain at the desired take off angle and direction as the vertical but that is subject for another discussion).

If you work local line of sight HF you will get the same polarization issues that you get with VHF/UHF.

With all due respect, and I know each configuration has its own characteristics, but I think coiling up some coax into an ugly balun is easier to try than finding a new instalation for the antenna. My shack is on the second floor, about 15ft below and 10ft east of the feedpoint. If what I experienced was rf from the antenna, I doubt it would have disappeared by adding the choke, which I did at the suggestion of some experienced hams. If I understand it right, this type of antenna is prone to feedline radiation. The "Carolina Windom" version actually uses a portion of the coax shield for radiation, with a choke installed about 22ft down from the feedpoint, IIRC. I mean no disrespect, I just think that an ugly balun would be an easy thing to try before moving the antenna.

40..like i said the shack is in the basement now right above the shack is the tv and the balum is above that(out side) so the rig- tv and balum is all in line together .and i am in a small lot i cant move the balum the xyl wants the tv to stay put and if i move the shack i will haft to buy more coax and redo the hole thing .witch would be ok to move but it will be a hassel. but it can be done

6432. Install question

Yahoo group: ham-antennas (2008)
Date: 2008-10-23 00:09:10 UTC
From: Ken K6KAW
Topic: 6432 Message: 6432

Greetings to the group. Having just passed my general I still have lots of questions.

I know that for good performance that a dipole should be 1/4 - 1/2 above the ground.
Does that also mean that it should be that height above the top of my building?
Just a little background I live in a 2 story apartment building. I do have permission
to put up an antenna, I just think I should keep it low profile.

73 K6KAW

From: John P.
Topic: 6401 Message: 6433

There are some good discussions in the ARRL antenna handbook. Also, if you search via Google, for the 3 key words - dipole radiation pattern - there are some really fantastic diagrams and information out there.

Suppose you have a dipole hung as an inverted V....what is
the "effective" height of the antenna when used to calculate the RF
radiation patterns?

From: hochman_97
Topic: 6432 Message: 6435

Hi Ken,

I'm sort of new at this myself, but the way I understand it is this....the "height" relates to where you choose to put the ground plane below the antenna. When the vertical is above an "ideal" ground the resonating charges in the real vertical causes "mirror virtual charges" in the ideal ground plane. Essentially the ground looks like a mirror with an "effective" reflected 1/4 vertical resonator in it. This might sound weird but it's how my professors explained it to me back in "the day".

We put up a Lot of hardline in the cellular
systems. A simple way is to double rap the
hardline to the tower legs with #12 cu wire.
It is cheep and easy to use. Cut a number of
pieces about 12 to 18 inches long .. bend them
in half and hook them to your belt then go
up the tower and rep the hardline from the
top down.

From: Bill
Topic: 6399 Message: 6437

Glad you found the problem, Phil. That's always a good feeling. Now here's the next thing...

Some of the stuff I've read says that the choke is more effective if the coil is wound flat around a form instead of bunched up. I think 18' to 20' around a 4" dia piece of pvc is supposed to be good from 160m to 10m, but do some research, I might be off in my recollection. There is definitely plenty on the subject online.

I actually took down my OCF and put up a 135' dipole in its place, fed with 300 ohm twinlead. Great reports so far, but I'm limited to pretty much a N-S orientation. I think I'm sending more signal toward africa instead of europe. I'm sure working africa would be great, but haven't heard much out of there. The OCF, when modeled, has some real funny lobes getting some of the power toward europe, and with that antenna I've worked 26 countries since Feb, with only a couple outside of europe. I think my next experiment would be to put up the OCF and feed with twinlead just to see how it works. The 4:1 would then be at the shack, instead of at the feedpoint. I just looked up online to see if anyone has tried that. Between that and some thinking on the subject (it is actually feeding an "unbalanced" antenna with a balanced transmission line) I'm pretty skeptical of the results, but I will probably try it anyway. I'll try and post results.

Have fun!

There is a QST article by K4ZA from the May 1997 QST magazine titled
"A Skyhook for the '90s". This article also has a Bibliography for
several other related articles on ballons. I saw it in the ARRL
book "More Wire Antennas Vol II".
Also you could do a search of QST magazine on the ARRL website.

My wife, bless her, was really nice about the LMR400 that I have running here and there.

Of course I don't say anything about the collection of Eeyores either....

6441. lower height requirements for long wave (160M) bands?

Yahoo group: ham-antennas (2008)
Date: 2008-10-23 17:39:15 UTC
From: hochman_97
Topic: 6441 Message: 6441

I've been researching antenna configurations for 160M TX/RX and it looks like most require mounting the antenna pretty high up. I'm somewhat restricted in my ability to get a dipole (or other configs) up higher than ~30' or so. I realize that this is nowhere near 1/4 wavelength of height at 160M, but I'm wondering if there's a way to setup the antenna to operate at a more "humble" height? I guess I could try a horizontal longwire configuration, but I'm not sure what the downside of a horizontal polarization to my signals would be...likely signal degradation I'm guessing. Although, I'm guessing a long dipole with radiators hung at 90deg to the feedline...up as high as possible might work if the radiator elements are 1/4 wavelength long, but I don't know how well that would work out. Has anyone heard of a usable/efficient lower band antenna that doesn't require hanging some element ~100' up in the air?

Try inverted V at 30 ft. Somewhat omni-directional. But you will work some DX with it. If you can install a Beverage antenna at 8 ft high for receive you will do even better since it is a low noise on receive. If you can hear them, you can work them.

Best Regards
Dan Schaaf

EZnec does indeed have a theoretical lossy ground, as well as a perfect ground. Although I haven't used EZ for a number of years, since I now run Linux, but I remember using it, and it performed pretty close to actual for my QTH. In fact, it was more realistic than the Linux version I am now using.

6446. noise help

Yahoo group: ham-antennas (2008)
Date: 2008-10-23 22:02:59 UTC
From: Its from KE4VYN
Topic: 6446 Message: 6446

Hi guys,

Apologies if you cant see pics.

If you have a second for me to run a issue past ya.

I know noise is always a problem, but what I have done to get get a 'ground zero' like we used to do in tv stations
is run a piece of #6 copper from the battery to the antenna ground.

Like this. That way I have a direct run.

Then along the way I attach parts to 'Ground zero', like cab, frame, and tailpipes.

Then another attach at the frame/cab factory ground.

I read 2.3 ohms from this point to the inside of cab at radio chassis ground/antenna shield.

Now here is the weird part. going from battery to first point I get 9 ohms!!!!

I mean this first point is only 2 feet from the battery! Right behind the wheel.

Any ideas???
Got S7 noise with engine running and 0 with it off. Sounds like hash noise, not whine.

Lee

6449. PVC plastic pipe strength and stability...

Yahoo group: ham-antennas (2008)
Date: 2008-10-23 22:28:32 UTC
From: hochman_97
Topic: 6449 Message: 6449

I was thinking about making an antenna with a long section of PVC pipe mounted on it's end (on the ground) pointing up to some height. The question I have is, does anyone have any experience with this stuff and know how tall such an arrangement can get before the top section becomes fairly "bendy" and wobbly/unstable? I experimented with some narrow diameter PVC pipe and it looked pretty unacceptable for any height above about 10'. I'm guessing bigger diameter pipes would work better, or possibly be just as bad...not sure.

Your are pretty close - 10 to 15 feet max with two PVC pipes telescoping.
The problem is that you have to use guy ropes in the middle of it to keep it from bowing.
I use surplus fiberglass cammo net poles available on e-bay and elsewhere.
Much stronger than PVC.
About 4 feet a section and six of them together are pretty self-supporting and with little luck will go higher.

You might try sliding smaller sizes into larger sizes and use schedule 40. I heard of people getting 30 ft using this method. I've never tried it my self..good luck, Alan

Dale K8TS hr:
I work with it every day. Schedule 40 does have some strenght but not that much. In fact I just got through mounting a similar set-up myself. I used a GM 8' tower mounted on my roof. I used the rotor plate as the bottom plate for the mast. I then used a section of 2" SCH 40 (5') as the lower link going throught the top. Inside the the 2' I inserted a piece of 1 1/2 pipe which fits nicly. I mad about a 2' overlap and instead of using a coupler I used a Ferco fiting (a rubber connector), with a weatherhead on top. From this I hung my 160 antenna. There is some pronouned bend in the pipe combiniation. Not sure that the pipe will last through the winter cold. If I had thought to I would have used SCH 80 conduit as it is UV protected. That's my experience. 10' sections will definitly not hold up

> building?

It is mostly the earth that matters, or maybe the water table. But this depends on what the building is made out of. That's why many people can use attic antennas. The wiring in the building has some effect but it usually isn't overwhelming.

On the other hand, if the building has a metal frame, an antenna above the roof might see the building as its underlying "ground" structure (especially if the building is longer than a wavelength) and then it's the height above the roof that you want to worry about.

A horizontal antenna 1/2 wave above good ground causes a null in the pattern straight up, which can mean so-so results working local stations, but good DX. An NVIS antenna (cloud burner) does the opposite, to hopefully eliminate the skip zone and let you communicate reliably with stations within a few hundred miles.

If you have a manual antenna tuner, keep the rig in RX and adjust the tuner to peak the received signal (or noise) at the frequency you want to use. That will get you in the ballpark, and it's better than randomly transmitting and seeing how many people you can contact.

If you have an automatic tuner, it will try to minimize the SWR once you transmit.

It is important to realize that an antenna tuner doesn't minimize the SWR unless it is adjusted right. *IT* doesn't try to minimize the SWR. YOU do that, by adjusting the antenna tuner for low SWR.

And I think you asked what the SWR is like on the other side of the tuner. The antenna tuner has no effect on that. But that doesn't matter (unless you are concerned about feedline loss).

Andy

Well, when I mentioned my antenna tuner...I was referring to an automatic one (should have said so..sorry). So the automatic antenna tuner does try to minimize SWR to the radio, but as I was mentioning before..that doesn't mean that the power from the transmitter radiates out of the antenna...it can actually be going to produce heat...depending on reflections back from the feedline/antenna after the tuner. I was just wondering what a good/cheap way to adjust a new vertical would be since my antenna tuner (built into radio) mostly reads that the SWR < 1.5 or so..and my automatic tuner doesn't have any display at all just an LED that turns on without flashing if the SWR is low enough. Maybe I just need to get another SWR meter with an actual readable scale on it? ;-}

All I can say is use what you can get up. Anything that radiates a
signal is better than sitting and pondering "what if". You can put a
G5RV up at only 30' or so, higher is better, but it will work some. Get
on the air and have some fun.

dear dennis
i had great success with my fullsized topband loop .... if you have the space for it , you should try it
i work with it on ANY band ....
for 160 it is a cloud burner cause it is only 10-12m of the ground but on the higher bands it rocks :-)
i use abt. 168m of alluminium fence wire and windowline to feed it in the tuner i have a 1:9 balun homemade and for most of the bands i don´t need to use the tuner
just the balun switched in but tuner switched to off ....
i have abt 18m of windowline from the feedingpoint to my shack and another 20m that is hanging circular under the roof of my house
for 160 i use abt 38m of windowline to transform the feeding impedance to abt 450 ohms
for 80m i use abt 18m of windowline
for 40 i use sometimes the shorter and sometimes the longer run (depends on frequency)
....after that comes the balun to transform from 450 to 50 ohms
on the higher bands sometimes the longer sometimes the shorter run of windowline
swr is very very low on most of the bands
i made an excelsheet for my notes and if interrested i can load it in the file area
but you surely need the space to hang that huge antenna :-)
"if you have the space for a dipole you have also the space for a loop"
just take another piece of wire and close the ends of your dipole to form a loop
feedingpoint is over the roof of my house on a 6m tv mast with a pulley
one side is going in a tree at the end of my garden (60m)
and the other side is on a wodden pole abt 40m away from the house
the third side is between the wodden pole and the tree abt 70m
i tryed 3-4 days with diffent lenght of windowline and cut and try cut and try .....
but now i have an ALL-BAND-antenna that really works great
good luck on dxing
best 73´s de dg9bfc

Betreff: [ham-antennas] efficient, easy to build or install dipole wire antenna that will cover 160-10

Hello every, I am new to this group. I need some expertise from someone who has built and used efficiently a dipole antenna.

I want to put up a dipole that will cover 160 meters thru 10 meters. I have limited space but do have two pine trees about 120 feet apart and a elm or maple that is off set but kind of centered between the pine trees. In the back yard, the yard is short but the trees and woods go back about a block or even more.

The problem I am having is getting the antenna up at least 30 feet or more. Prostate cancer and other medical issues are preventing me from throwing like I used to. I seem to be able to only throw about 20 feet up if that much.

I was absent from ham radio for almost 3 years and am just getting back on. My station consists of an ICOM 735 transceiver, an Astron RS20A power supply, an MFJ 949E Delux Versa Tuner II. I will be running only 100 watts.

MY FAVORITE BAND IS 160 METERS. I want to be able to use all bands and I have been looking at several manufactured antennas, but I have limited financial resources due to the medical issues.

I have enough 14 gauge insulated stranded wire and nylon cord to pull the antenna up and tie it off. I don't seem to be able to locate the 300 ohm twin lead as no one locally has heard of it. I think I would also need a balun at the bottom of the 300 ohm twin lead. Need to know who makes the best and most efficient one. I already have the coax cable from inside the shack to outside which is RG8x. However if I need to run the twin lead directly to the tuner I will have to modify somewhat which isn't a problem.

Sorry for the lengthy post

In Advance Thank You and 73s
de K0CKDennis

I can provide a photo of the limited space and would send the same if you correspond to my email address of dennisissure@...

I gotta agree here -- my antenna is only 20 feet up and I have had some amazing contacts on 160 meters, and some outright spooky DX contacts on 80 meters that I never would have expected -- Ireland, England, France, Costa Rica, and even Ducie Island. Put something up as well as you can and remember -- "run what ya' brung"!

Consider using pvc pipe but only use sch. 80 pipe ,not sch 40 like found in home depot etc. would guess 3 to 4 times stronger.

Subject: [ham-antennas] PVC plastic pipe strength and stability...

I was thinking about making an antenna with a long section of PVC pipe mounted on it's end (on the ground) pointing up to some height. The question I have is, does anyone have any experience with this stuff and know how tall such an arrangement can get before the top section becomes fairly "bendy" and wobbly/unstable? I experimented with some narrow diameter PVC pipe and it looked pretty unacceptable for any height above about 10'. I'm guessing bigger diameter pipes would work better, or possibly be just as bad...not sure.

I have used schedule 80 but it needs guying generally for the smaller sizes at 15 to 20 foot here on our hill top in SC or an internal support works well also

Consider using pvc pipe but only use sch. 80 pipe ,not sch 40 like found in home depot etc. would guess 3 to 4 times stronger.

Subject: [ham-antennas] PVC plastic pipe strength and stability...

I was thinking about making an antenna with a long section of PVC pipe

mounted on it's end (on the ground) pointing up to some height. The

question I have is, does anyone have any experience with this stuff and

know how tall such an arrangement can get before the top section

becomes fairly "bendy" and wobbly/unstable? I experimented with some

narrow diameter PVC pipe and it looked pretty unacceptable for any

height above about 10'. I'm guessing bigger diameter pipes would work

better, or possibly be just as bad...not sure.

From: Andy
Topic: 6370 Message: 6468

I also wanted to add that, if an antenna has good SWR somewhere in a band, then in many cases it will be OK in that entire part of the band.

(That tends to be less true for shortened or compromise antennas which have sharper resonances.)

So yes, there is one frequency where the SWR is lowest, but if it remains low (say below 2:1 or 3:1) over the band, then you should be all set and don't need to worry about finding that one frequency where it is best.

An SWR meter is not a bad idea ... as long as you don't get fixated on it. Many hams do fine without SWR meters.

Andy

i have gone to 30 feet using pvc tubes by putting a piece of wood inside as a stiffener a 2 by 2 works well in a 2 inch tube , you doo not need to join them they only act to stiffen the pvc but you still need to guy them at least once or twice depending on the length

Your are pretty close - 10 to 15 feet max with two PVC pipes telescoping.
The problem is that you have to use guy ropes in the middle of it to keep it from bowing.
I use surplus fiberglass cammo net poles available on e-bay and elsewhere.
Much stronger than PVC.
About 4 feet a section and six of them together are pretty self-supporting and with little luck will go higher.

but at the same time don't forget if the swr is really good with little
change across the band look for losses. No antenna is truly wide.
except for a dummy load.

Lee, just for chuckles, try reversing the meter leads. Since ohm meters actually measure voltage drop across, or current through the resistor under test, what you may be seeing is the effect of the voltage drop caused by the normal current drain to the vehicle's circuitry through that piece of wire.

Good hunting,

Stan

Subject: [ham-antennas] noise help

Hi guys,

Apologies if you cant see pics.

If you have a second for me to run a issue past ya.

I know noise is always a problem, but what I have done to get get a 'ground zero' like we used to do in tv stations
is run a piece of #6 copper from the battery to the antenna ground.

Like this. That way I have a direct run.

Then along the way I attach parts to 'Ground zero', like cab, frame, and tailpipes.

Then another attach at the frame/cab factory ground.

I read 2.3 ohms from this point to the inside of cab at radio chassis ground/antenna shield.

Now here is the weird part. going from battery to first point I get 9 ohms!!!!

I mean this first point is only 2 feet from the battery! Right behind the wheel.

Any ideas???
Got S7 noise with engine running and 0 with it off. Sounds like hash noise, not whine.

Lee

Yes, and as we know ohm meters act twiggy around other powers sources anyway.
were actually on to a couple of things, moving the coax to the other side away from the computer.
Also choking the DC supply line are the next steps.

We tried analyzing the noise and found it strongest at 5.6Mhz and 28.3Mhz. so wee going to bond the battery to 'ground zero' /frame, something that Ameritron flatly says not to do and go from there.

Noise is always a two part problem, figuring what noise it is and draining it to ground.

Why I love radio! (hack...hack...cough...cough...)

Another consideration...

Go to Lowe's or Home Depot and check the top railing of the wire fencing. They come in 10' sections. Two of them are pretty strong. A section of 1-1/4 inch pvc slips over it pretty tight. But you should probably slip in down two or three feet and then secure it with a couple of good metal screws. That would put you up about 26 feet.

It's not perfect, but it's a pretty sturdy get-you-by.

Hello,

I have a Triex T471 guyed crank up tower. It consists of four
6 meter sections for a total extended height of 21 meters.
Made ca 1980.

I want to sell this tower but I have no idea what price I should
ask. The tower is on La Palma island, Canary island group, but
a price in the US or UK will at least give me some guidance.

Thanks!

Yes, try reversing the leads to your ohm meter. Oxidized metal can act as a rectifier (I can remember when we used copper oxide plates in high power power supplies.)

I successfully went up about 27' with sked 2 pcs sked 40 4" PVC and a 7' pc of 2" when I built a 15 m loop that just worked like a champ!

It would have been waaaayyy wobbly if I had not been able to brace it at 8' to my yard barn...I also guyed it at 20'.

However, I like my 35' mast made from 2" and 1-1/2" thin wall conduit much, much better...It is attached to my house at about 18' and has one guy countering the pull of my G5RV.

It might have been a mistake , on another electronics based group someone made a statement about the price of copper, I replied he should check the price today as he was a few months behind and copper had dropped so the dollar amount for copper scrap would be lower. This looks like a follow up to that thread but in too much detail??? It was not from me.

Hi to all,
Just found and joined the group this weekend. By way of introduction, I'm mostly an HF DXex and 100% cw op. Got started as a teenager (40+ yrs ago). I belong to FISTs and SKCC and the local DX club (SEDXC) in the Atlanta area.

Enjoy experimenting with antennas, towers, etc. (and if its' okay to mention, I also make TiltPlates for tiltover towers)

6484. RF in the shack-----IC-735 shuts down

Yahoo group: ham-antennas (2008)
Date: 2008-10-26 14:33:05 UTC
From: Dennis G. Peterson
Topic: 6484 Message: 6484

Okay guys, I hope I'm in he right place to ask these questions. Having been away from ham radio for 3 years wiith medical issues i.e. cancer; I need to find out why I am experiencing some of th issues I have with my new set up.

1 I installed a new antenna yesterday, Saturday Oct.25, 2008. There weren't very many choices to choose from due to various obstacles and interfering conditions. I finally was able to get a 135' wire to the top of a pine tree. This wire from the feed point to the top of the tree is 90' and then the horizontal part is 45' long and support some 80' away thru the top of another tree and the tie off line down so it can be removed or lowered etc, etc.

2 This 90' vertical wire is not exactly vertical. From the bottom of the tree to where the feed point is, it must be around 20 or 22'. In otherwords it rather slops itself for about 25 feetbefore going truly vertical. I don't think the angle or slope is any more than maybe 12 or 14 degrees at most.

3 The antenna is fed with coax(RG58). It is fed against a ground radial system consisting of 4 ground radials approximetely 30' long. Not much yrd space in the back yard for radials. I do plan to add some more later. The feed point is rather crude riht now until I can get a permanent feed. The coax is hard wired to the radials and antenna wire. And it is also connected to the ground rod of the station ground. (A) IS THIS CONNECTION CAUSING AN RF IN THE SHACK PROBLEM?

4 I can tune the antenna on any band and get the swr down and the antenna to resonate to nearly a perfect match on all bands as long as I USE ONLY 15 WATTS OF POWER. there are only a couple of bands where the swr or resonance is not nearly perfect, but 1.5:1 which is okay. If I attempt to more the RF power slider on the front of the 735 to max power of 100 watts, the 735 shuts down. When and while adjusting the tuner for resonance,I have touched the back side of the TX or antenna tuning knob and got bitten by RF. This is USING A mfj 949e TUNER which is supposed to handle 300 watts. The tuning is rather sharp and touchy as several adjustments have to be made to get it down. I have more time than I do MONET!

5 My favorite band of operation is 160 meters. I thought aout putting up a simple vee for 10-80; but knowig I wouldn't be happy I kept after possible alternatives, thus settling for the antenna I described. I guess I need to take a photo of the antenna with the angle of vertical orientation and the horizontal portion nd post it.

Can anyone suggest some areas I might check to fix or cure this problem, short of telling me to blow it up and start all over. I am starting over and it's not easy the second time around after fighting cancer and medical issues. I can only run 100 watts of power as I can't afford an amplifier. The 735 is a nice radio as is the 949E tuner. I just need to resolve what is probably going to be some simple issues that I have forgotten over my 33 year ham career.

Sorry for such a lengthy post, but short of not telling all; it's the only way I know of being throoughly explicit and detailed.

2 ideas come to mind right off, use a common mode choke as it sounds to me like you have current on the shield of the coax, the other is to use twin ohm feed line to reduce losses. Try the first idea and make about 8 turns of coax about 8 inches in diameter assuming RG 8X a bit bigger if RG 8 or 213 Add more radials if they half to be 8 footers use them and that should help SWR is not always a sign of radiation you can have a good SWR and all the energy heating the line if your junction point is just right, and make the feedline into a dummy load.

Subject: [ham-antennas] RF in the shack-----IC-735 shuts down

Okay guys, I hope I'm in he right place to ask these questions.

Having been away from ham radio for 3 years wiith medical issues i.e.

cancer; I need to find out why I am experiencing some of th issues I

have with my new set up.

1 I installed a new antenna yesterday, Saturday Oct.25, 2008.

There weren't very many choices to choose from due to various

obstacles and interfering conditions. I finally was able to get a

135' wire to the top of a pine tree. This wire from the feed point

to the top of the tree is 90' and then the horizontal part is 45'

long and support some 80' away thru the top of another tree and the

tie off line down so it can be removed or lowered etc, etc.

2 This 90' vertical wire is not exactly vertical. From the

bottom of the tree to where the feed point is, it must be around 20

or 22'. In otherwords it rather slops itself for about 25 feetbefore

going truly vertical. I don't think the angle or slope is any more

than maybe 12 or 14 degrees at most.

3 The antenna is fed with coax(RG58). It is fed against a ground radial system consisting of 4 ground radials approximetely 30' long. Not much yrd space in the back yard for radials. I do plan to add some more later. The feed point is rather crude riht now until I can get a permanent feed. The coax is hard wired to the radials and antenna wire. And it is also connected to the ground rod of the station ground. (A) IS THIS CONNECTION CAUSING AN RF IN THE SHACK PROBLEM?

4 I can tune the antenna on any band and get the swr down and the antenna to resonate to nearly a perfect match on all bands as long as I USE ONLY 15 WATTS OF POWER. there are only a couple of bands where the swr or resonance is not nearly perfect, but 1.5:1 which is okay. Wow, I remember back in the early '80's I had similar problems and no
idea how to fix it -- the microphone on my Atlas 210X used to bite my
lip when using it at home with a low dipole!

My initial thought is to try coiling some of the coax to make a choke
for the shield. This is easy and FREE and sometimes it's all you need.
Do it close to the feedpoint. Good article with good pictures at
<http://www.hamuniverse.com/balun.html>

My second thought it ferrite beads to make a more effective choke --
see at
<http://www.dxengineering.com/Parts.asp?ID=289&PLID=182&SecID=89&DeptID=33&PartNo=DXE-CSB-
525P>

Just order up a set and try putting one of them on your coax near the
feedpoint. This has solved several problems for me when using HF mobile.

This company also has other sizes available -- see their search results
at
<http://www.dxengineering.com/Search.asp?Action=SrchKey&KeyWords=ferrite%20beads>
-- your RG58 will probably need a bit smaller bead, but I'm not sure
their smaller size will fit. You might end up using the larger size and
a couple of cable ties to hold them where you want them.

Hello Dennis,

Just a question of why you are tunning the antenna with 100 watts? At that level the reflected power while tuning is probably is probably causing the rig to shut down to protect itself. Tuning at 10-20 watts and then switching to high power shouldnt effect the swr little if at all.

Hi Dennis,

You gave a lot of info about your antenna and set up but nothing
about your "station ground".

There's no way you should be getting bitten...not at 100 watts...Fix
that and I'm pretty sure your shutdown problem will go away too.

Several potential problems come to my mind...

1, your station ground set-up,
2, how the parts of you station are connected to your "station
ground",
3, is your station ground "bonded" to your service ground...
AND, there are other things that may come into play...

But, getting bitten while running no more than 100 watts...no way
that should be happening.

As the members of our local club know, I'm kind of a stickler
for "proper grounding AND BONDING!

are you using a switching power supply at 40m or 20m bands?

if so that may be the problem as those supplies have spikes at those frequencies.

It might have been a mistake , on another electronics based group someone made a statement about the price of copper, I replied he should check the price today as he was a few months behind and copper had dropped so the dollar amount for copper scrap would be lower. This looks like a follow up to that thread but in too much detail??? It was not from me.

6493. Okay, here goes some of the answers

Yahoo group: ham-antennas (2008)
Date: 2008-10-26 22:18:21 UTC
From: Dennis G. Peterson
Topic: 6493 Message: 6493

First of all, thanks to those of you who sent and answered some of the uestions.

1 The power supply is an Astron RS20A (NOT SWITCHING)
2 The station ground is a 10 foot length of RG-59 coax with the center conductor and shields shorted together and connected to each piece of equipment and exiting the shack via a 3/4 inch hole in the floor and then to the power company ELECTRICAL Ground
rod to connect the staion ground to. Hence, the ground radial system is connected via a 15' radial to the ground rod.
3 As for the 735 shutting down; while tuning with 15 watts of power and achieving resonance and then raising power to 100 watts, THIS is when the problems seem to occur.
4 I see many articles as to the diameter of the choke balun i.e. 2.5"-----3"-----4"-----and 5" PVC. Which one is best to use over the others? Does it have to be a perfect circle or oval? IS THE LENGTH CRITICAL AS FAR AS 20 FEET OF COAX?
5 Also, a correction of the swr measurements are as follows: 160ssb @ 1860 IS 1.4:1 AND the 80ssb @ 3850 is 2.0:1
6 Does ANYONE KNOW of the availability of a trouble shooting guide for the 735, most manufactures include this in their manuals, I don't seem to find one for the 735 unless it is in the service manual.
Thanks

Dennis

6494. Re: [ham-antennas] Okay, here goes some of the answers

Hello again Dennis,

Did that power supply work before with the 735? The reason I ask is that most of the 100 watt radios I have seen (dont know about 735) use 20-22amps @ 100 watts. Is anything else connected to the supply? I was told a 25 amp supply should be minimum for a 100 watt radio. Have you tried @ 50 watts and scaled up to see where the cutoff is? I'm just tring to eliminate the power supply.

From: kb8uum
Topic: 6496 Message: 6496

Guys,

I am new to the group and have a few questions. I just received an SGC 239 tuner from home and was wondering if anyone has tried any multiturn loop antennas with it? I can play around with a few different sizes, a 5x7 or 5x20. I have tried some end fed halfwaves, but no luck to date. Any other antenna suggestions are also welcome. Briefly, I am on the second floor of an apartment building with no balcony to work with or trees, etc, about six blocks from the White House. Looking forward to hearing from you.

Geoff, KB8UUM

That's plenty power for a 100watt rig...

Yes, peak power will demand more current, but, nothing more than the
intermittent cpability of even mediocre 15 amp linear supplies...
I get the nonsense all the time that a 100 watt ssb rig needs a 25
amp supply...My 15 amp Icom supply handles my 746Pro just fine, even
on CW

Besides that, the power supply capability has no impact on getting
bitten on the back of your radio....

That brings up the next point...

Your ground/bond system is totally inadequate!

While you probably should use the #6 wire per NEC for your ground,
you will see much improvement over the "coax" ground with even a #10
solid wire.

And that still begs the question about how your equipment is bonded to your ground, and, also, very importantly, how you're bonded to your service ground.

I think if you get your "grounding" squared away, you won't have the "biting" problem anymore, and, that will probably take care of the shutting down issue.

Also, I would highly recommend NOT jacking your antenna tuning controls while running at full power...the resulting voltages and/or currents could easily trip the protection circuits of modern 100 watt rigs...

The transistorized rigs "want to see" 50 ohms RESISTIVE!...not 25 ohms reactive and not 200 ohms reactive.

The service manual may not address problems outside your rig!

Hi Mark,

They used to be available in the USA a few years ago. I had the 3-el version and it worked fine, good VSWR on the three bands. Basically just like any other 3-band beam. Well constructed.

John

OK, so over the weekend I picked up a Hustler 6BTV vertical. I read some really good reviews about this antenna which convinced me to give it a try. Anyhow, now the question I have regards tuning it...I've read that, in general sometimes it's necessary to use grinders and hack-saws to shorten elements of antennas to get them into resonance at a preferred location within the bands. I'm wondering if this is absolutely necessary in most cases? I'm wondering because it's possible that I'll want to use the antenna in several locations and possibly need to retune it over time..and a hack-saw/grinder seems like a fairly permanent modification to the hardware. Also, since I've read that the ground radial arrangement can affect tuning as well I don't want to do anything permanent (READ: non-recoverable) to the antenna. Thanks.

No NO NO NO DO DO REPEAT DO NOT NOT NOT CUT. Go to the DX Engineering website and they have an outstanding step by step instructions for tuning your Hustler. It is very simple. Please do not cut your antenna.

The basic instructions on tuning Huster antennas are at:

http://www.dxengineering.com/pdf/hustler_4btv5btv_instl.pdf

Here's the interesting part - if you can't get it to tune well with the given dimensions and a bit of adjusting, you may need to calibrate the traps. This is done by loosening the lower clamp previously where they told you "do not loosen". Try the first methods first, however. These additional instructions are:

http://www.dxengineering.com/pdf/Tuning%20the%20Hustler%20BTV%202008.pdf

I had to do this to get my 5BTV to resonate when it was mounted over a metal barn roof with minimal radials. Make very small adjustments - a little goes a long way.

Hope this helps,
-Dave

6504. Octagonal Beam

Yahoo group: ham-antennas (2008)
Date: 2008-10-27 23:21:50 UTC
From: john baker
Topic: 6504 Message: 6504

Hi guys,
New to the group and looking forward to trying some new things.
Some 8-10 years ago I remember reading about a quad or box antenna having at least 3 elements. Each element was shaped like an iron cross, or the outline thereof. This was supposed to be a variation of an 6 or 8 sided element design that had been proven but this particular shape was to make the overall size much more compact. In the area I have to place a tower, I remember thinking that this looked ideal to keep from encroaching over the fence to my neighbors yard.

Problem is, I can't find a clue as to the plans for this antenna. I have googled myself stupid. Can't think of any other descriptions to use for a search. I thought I saw it in QST magazine. Can't find that issue...or remember which it is. Does anyone happen to know of or remember such a design?

thanks

Try the URL below. It's for compact quads, at least one of which is shaped like a Maltese Cross.

I'm wondering if I can use this setup?

radio <-> antenna tuner <-> SWR meter <-> antenna

Basically I want to ensure that my radio never sees a bad SWR while I'm tuning my antenna. I know, fairly paranoid...but I want to be kind to my radio's transistors =)

I know the conventional way to do this is probably...

radio <-> SWR meter <-> antenna

and then rely on the radio's rollback circuit if the SWR is too out of spec. Oh yes, by the way...does anyone have any experience with feedline current chokes, how is this different from the recommendation in the manual to use several coax turns at the base of the antenna?

Nope, not for what you want at least

Radio-swr-tuner-antenna

The swr bridge there will tell you if you have matched the rig to the antenna with the tuner/coupler.

Most rigs and tuners have an swr meter in them though.

Also, you should be tuning with very little power anyway. Once matched, turn up and go.

Never work a rig intentionally into a bad mismatch either, it's just plain foolish. Protection circuitry is there to prevent accidental damage, not to increase the number of lid operators ;-).

Yea, but the SWR meter will be telling you the VSWR of the coax/antenna,
and not what the radio is seeing. If the antenna tuner has a built in
SWR meter, then sure, why not? but if you need to know what the radio is
seeing, then move the meter between the radio and the tuner.

Hi Steve,

But isn't this what I'm looking for? I mean I need to know the VSWR of the coax/antenna (since I'm assuming the tuner will try to make the radio think it sees a good SWR ~1-1.5 even if I'm trying to tune a rock). What I really want to do is figure out if the antenna/coax system is setup correctly to radiate RF in the freq/band of interest.

Well, sort of. What the "tuner" is doing is fooling the radio into

thinking it sees a 50 ohm load. The antenna tuner adds either inductive or capacitive reactance to the network, which consists of your antenna and the feed line, to compensate for whatever is missing. If you system has capacitive reactance, then inductive reactance is added to trick the radio into seeing the proper load and visa versa. So, you do need to know what the radio is seeing. But, if your match box has a built in SWR meter, or if the radio has one, then adding one after the tuner, in line with the feed line doesn't hurt. It will tell you a couple of things that you might want to know. If weather effects a change in your network, the tuner would mask this, but having an SWR meter between the tuner and the coax going to the antenna is a good idea. It will show you just how much SWR is changing due to weather. It also might alert you if there is a sudden change in your system such as wind damage. I have had a problem with big birds (wild guineas hens) wanting to perch on my wire antenna. These birds weigh about 10 pounds (5 kilo) each, and a flock of 4 or 5 will sit up there at times. They have broken the wire a couple of times. If I had an SWR meter after the tuner, I would know when this happens again. My antenna tuner is an automatic, so I don't get a visual indication of where the knobs are.

From: n1kfc
Topic: 6514 Message: 6514

Hi,

I picked up one of these old antennas in good shape, except for the whip. The antenna is similar in appearance to the MFJ Balcony antenna but uses a variety of user selectable coils rather than a tuner.

Does anyone have any info about this antenna? B&W no longer makes this antenna. I also would like to source a replacement whip or adapt an MFJ whip for the purpose: from 3/8 x 24 to the post on the B&W. Any information would be appreciated.

73,

From: dennisissure
Topic: 6515 Message: 6515

Over the weekend I put up a Marconi type vertical antenna. It was pulled to a height in a pine tree of 90 feet. The antenna has a total length of 129 or 130 feet with the remaining 49 feet horizontal at 90 feet.

It is fed at the bottom with coax to a rather modest small ground radial system and 1 quarter wave radial about 130 feet long stretched out through the woods at the back of the property line.

I guess I was hoping for a miracle of sorts when the antenna was installed so I could operate all band 10-160 meters and preferably 160. The equipment here is an IC-735 transceiver powered by an Astron RS-20A Power Supply. The 735 has an output of 100 watts. The tuner is a MFJ 949E Delux Versa Tuner II.

I am only able and capable of running this type of equipment right now due to other reasons. The problems at hand seem to be minor, but due to the medical issues over the past 3 years; I might not have a clear thinking mind these days so I am asking for some advice. Here are some of the issues

1 The transceiver shuts down if power is over 50 watts and the SWR is high--------I assume some sort of protection device in the 735 if swr exceeds 1.8:1 or 2.0:1 SWR limikts

2 While adjusting the Transmit and Antenna controls on the tuner during transmit, if I accidentally touch the back side of the know which is metal I will get an RF bite and you can literally smell the skin burn LOL :>(

3 The station ground is a piece of RG58 coax with the shield and center conductor shorted together and run thru the floor and out to the electrical ground rod at the service entrance about 8 or 10 feet away. This coax is connected to each piece of transmitting gear, i.e. 735 and 949E.

4 I can tune the antenna by adjusting the 735 for an output of 15 watts and adjust the controls for resonance on various bands which I will show below.

5 Even with only 15 watts, I interfere with my girlfriends lamp in the bedroom and her tv as well, and the neighbors tv in the adjoining duplex. I have never haed a RF problem in 33 years like the one I am having now. I am going to try a different electrrical ground system for the radio gear and see if this helps. It seems to do this on all bands I try to operate on or adjust for resonance.

949E tuner caps are each 200pf caps fully meshed and the Inductor is a 2.5 or 3" diameter tapped coil with the bottom of the coil grounded and labeled clockwise A thru L. L being the tap farthest away from the ground end of the coil. In this tuner, A is on the bottom of the coil and L is near the top. Other tuners were different and the inductance switch showed a 180 degree opposition to this but that was earlier 949 models i.e. b,c and d

models. The 949E does have an 8 position switch a 300 watt dummy load and a 4:1 balan for ladder line feed antennas and an end fed antenna. I don't have 450 ohm ladder line and I haven't been able to find 300 ohn open tv twin lead to try balanced feed anywhere due to financial limitations.
No one around here seems to not have heard of it. I don't know how much I could afford if I did find it new and or used.

The settings below in BLUE are those readings taken upon initial testing of the antenna without a quarter wave counterpoise added.
The setting in BOLD are the new values after adding the counterpoise.

Spread Sheet of Ant. vs Tuner setting and results 10-25-2008

Band Frequency TXc L Antenna SWR after tuning
==========
160cw 1.833 5 3.5 A A 3 4.25 1.1:1-----15 watts 1.9:1 can't tune any lower for resonance

10ssb 27.900 7 I 3.5 1.0:1 " "
10FM 29.600 8 K 4 1.1:1 " "

The best way I can describe this antenna is as follows until I take a photo of it. Imagine a 90 foot pine tree. A 139 foot piece of 14 gauge stranded insulated wire pulled over the top with the remaining 49 feet pulled horizontal with an end insulator attached and nylon cord tied off to another pine tree. The bottom of the 139' wire which tapers away from the tree at about a 12 degree angle and 20 +/- feet away and fed with a piece of RG58 coax with the center conductor connected to the 14 gauge wire and the shield connected to the counterpoise antenna. I disconnected the small 4 or 5 short 15-20' ground radials. I was trying to find a software design, drawing program that I could possibly use but most are expensive and many of my ham programs that I had on a desk top PC were lost a few months back during a hard drive crash. Lots of programs I paid for now trashed.

If someone can tell me where I am neglecting to see why this antenna is not working, please reply. I know it has to be simple or I'm just blinder than I think.

Starting over isn't the easiest task after being a ham for over 33 years and especially after going thru a medical life changing experience. But who says life is easy RIGHT>!

Looking forward to solutions, relosutions, fixes or whatever. Thank for listening, evaluating and assisting me in this venture.

Dennis, probably the simplest fix would be to add a 1:1 balun at the antenna end of the cable, since you're relating all the symptoms of "RF on the shield".

It could even be one of the ugly baluns, a solenoid of coax, the dimensions for which can be found by Googling "ugly balun for 160".

As regards the station ground; suggest that you connect the shield of the coax directly to the ground rod before it enters you home... and add another ground rod ten plus feet away from the power co's rod (more is preferable). Better to shunt any lightning energy to ground before it has a chance to enter your house rather than having it flow through the equipment on its way to earth. But no, that will probably not help with the RF biting your fingers.

Good hunting,

Stan

Subject: [ham-antennas] Not doing so good

Over the weekend I put up a Marconi type vertical antenna. It was pulled to a height in a pine tree of 90 feet. The antenna has a total length of 129 or 130 feet with the remaining 49 feet horizontal at 90 feet.

It is fed at the bottom with coax to a rather modest small ground radial system and 1 quarter wave radial about 130 feet long stretched out through the woods at the back of the property line.

I guess I was hoping for a miracle of sorts when the antenna was installed so I could operate all band 10-160 meters and preferably 160. The equipment here is an IC-735 transceiver powered by an Astron RS-20A Power Supply. The 735 has an output of 100 watts. The tuner is a MFJ 949E Delux Versa Tuner II.

I am only able and capable of running this type of equipment right now due to other reasons. The problems at hand seem to be minor, but due to the medical issues over the past 3 years; I might not have a clear thinking mind these days so I am asking for some advice. Here are some of the issues

1 The transceiver shuts down if power is over 50 watts and the SWR is high--------I assume some sort of protection device in the 735 if swr exceeds 1.8:1 or 2.0:1 SWR limikts

2 While adjusting the Transmit and Antenna controls on the tuner during transmit, if I accidentally touch the back side of the know which is metal I will get an RF bite and you can literally smell the skin burn LOL :>(

3 The station ground is a piece of RG58 coax with the shield and center conductor shorted together and run thru the floor and out to the electrical ground rod at the service entrance about 8 or 10 feet away. This coax is connected to each piece of transmitting gear, i.e. 735 and 949E.

4 I can tune the antenna by adjusting the 735 for an output of 15 watts and adjust the controls for resonance on various bands which I will show below.

5 Even with only 15 watts, I interfere with my girlfriends lamp in the bedroom and her tv as well, and the neighbors tv in the adjoining duplex. I have never haed a RF problem in 33 years like the one I am having now. I am going to try a different electrrical ground system for the radio gear and see if this helps. It seems to do this on all bands I try to operate on or adjust for resonance.

949E tuner caps are each 200pf caps fully meshed and the Inductor is a 2.5 or 3" diameter tapped coil with the bottom of the coil grounded and labeled clockwise A thru L. L being the tap farthest away from the ground end of the coil. In this tuner, A is on the bottom of the coil and L is near the top. Other tuners were different and the inductance switch showed a 180 degree opposition to this but that was earlier 949 models i.e. b,c and d models. The 949E does have an 8 position switch a 300 watt dummy load and a 4:1 balan for ladder line feed antennas and an end fed antenna. I don't have 450 ohm ladder line and I haven't been able to find 300 ohn open tv twin lead to try balanced feed anywhere due to financial limitations.
No one around here seems to not have heard of it. I don't know how much I could afford if I did find it new and or used.

"swr exceeds 1.8:1 or 2.0:1"
I would think that this rig could take these levels. Maybe RF coming back?

The antenna tuner will make a low SWR *only* if it it adjusted correctly.

If it is a manual antenna tuner, you must have an SWR meter on the radio side of the antenna tuner, so you can tell how to adjust it for lowest SWR. If it is an auto-tuner then it *probably* will find the sweet spot giving the lowest SWR, and then you could assume that the radio indeed sees a good SWR. If your biggest concern is protecting your radio, then you ought to have an SWR meter on the radio side of the antenna tuner.

If the antenna tuner's losses are low, and if the coax losses are low, then when the radio sees a low SWR, it will be able to deliver the most power to the antenna. If the antenna's losses are also low, then the power that goes into the antenna will radiate from the antenna rather than turning to heat. It doesn't make a bit of difference what the SWR is at the antenna. SWR is a somewhat meaningless measurement anyway, since all it is saying is what the impedance is relative to a reference impedance, usually 50 ohms. Well, if your antenna is an endfed halfwave and is supposed to have a feedpoint impedance in the kilohms, then the SWR with a 50-ohm SWR meter at the feedpoint will be very poor. But such an antenna probably functions very nicely, if you match to it. High SWR at the antenna does not say anything about how well the antenna radiates.

As for antenna losses, if the antenna heats up, then it has losses. Antenna losses tend to make an antenna's SWR lower too. This can be a problem with verticals with buried radials where there aren't enough radials; the ground resistance (which is part of the antenna system resistance) is significant so a lot of the power goes into heating the ground and not "getting out."

> What the "tuner" is doing is fooling the radio into
> thinking it sees a 50 ohm load.

What it does is actually *give* the radio a 50 ohm load. It doesn't fool the radio. The radio really sees a 50 ohm load.

A transformer is one form of antenna tuner (though not an adjustable one). If an antenna has a 300 ohm feedpoint impedance, and a transformer exactly transforms the 300 ohms to 50 ohms, then it provides a perfect match to the rig. There is no fooling involved.

> Oh yes, by the way...does anyone have any experience with
> feedline current chokes, how is this different from the recommendation
> in the manual to use several coax turns at the base of the antenna?

They both do pretty much the same thing. Ferrite chokes can give you a greater common-mode impedance than you can get with an air-wound coil made from several coax turns.

Regards,
Andy

I can't say ... but I thought B&W also sold lots of antenna parts. Have you checked with them to see if they have any parts for that model that they may be able to sell you? Or maybe just a manual or some information about it, so you can cut yourself a new whip.

Andy

-Hi
I had a 6-btv until recently. It worked fine follow the instructions
by DX eng like the other post say and NO cutting please. Mine was
ground mounted with no radials only sold it due to wife wanting to
landscape the garden , things we do for women !

Exactly correct -- I used an RS-20S for many years on all my radios --
TS-430S, Yaesu FT-690R2, Icom 706, etc. Worked just fine.

DO NOT CUT!

Every one before my post is correct. I can't say it enough DO NOT CUT (or grind). I worked DXCC phone, cw, mixed, and two single bands with that antenna.. It will do you well. When doing my usual summer tune this year, I got brave.....decided to improve my 80M tip. HA! I tried grinding it (what did I just say?) to 3775~3800. It is now resonant at somewhere near 3900 Lesson learned: DO NOT CUT

Hi Andy,

Thanx for the reply. Apparently, the antenna is too old and B&W does not have any info about it or parts. I did find a copy of a service manual available for sale on another site but I think that it would be unlikely to have info about the whip. Unless I can find someone with a B&W whip in their junkbox, I will probably have to adapt a 3/8 x 24 threaded whip to the smooth post on the antenna mount. Thanx again for the response.

Mark,
I had on of those in the early 80's. The whip was a replacement auto whip that would go over a snapped auto antenna stub securing with set screws. It was designed for a 5/8 or 1/4 inch rod and was about 4' long. Loading coils were Miniductor stock for 20,15 and 10 meters and a large coil wound on a fiberglass form with magnet wire for 40. All slipped over the lexan rod. A marked 32 foot cpoise wire was supplied. You mounted the antenna and adjusted the counterpoise for lowest swr. It didn't work more than it did. B&W came out with a single coil on a pvc form that was clipped and marketed as the AP10.

From: john baker
Topic: 6504 Message: 6528

YES!! Thank you Harold!! That's it. Never thought of the word 'maltese' to use for a search. Nothing else I tried brought me to anything that I recognized.

Has anyone played around with these designs? The maltese cross configuration is the one that really interests me. I have a space of 12 ft for a side yard and, with the double-cross design and a tower next to the house, I should be able to put a 40 meter beam there without having it cross over the fenceline. If it all adds up..WooHoo! =) That is really going to help get into the Grants Pass to QSO with my Dad (ka7swi). It is at a distance where my verticle just won't do well on 20, 40 or 80 meters (sometimes on 40, very rarely on 20, more consistant but barely on 80)

Next step is to find a nice used collapsible tower. Word of anything in the Bakersfield area?

God bless

Lost the ball off a whip tip recently and replaced it with a teardrop shaped
piece of 2 part epoxy putty. I suggest that for a piano wire whip also.The
one I tried worked well and might save an eye.(G)

6530. Antenna Directionality???

Yahoo group: ham-antennas (2008)
Date: 2008-10-29 19:44:10 UTC
From: sward1961
Topic: 6530 Message: 6530

I'm in the process of making a multiband long-wire antenna for receiving only. Once assembled, I have the option of either stringing it baciscally in a north-south or east-west direction.

I would prefer to increase my reception basically from the east-west direction since I live in the central US. Should I string it in the north-south direction or the east-west direction to increase my reception from the east and west?

Any input will be appreciated.

height is going to be the first issue. If its up 100 feet high, then you might think about which way to point it. To answer your question though, wires are 'BASICALLY' omni directional
below 1 wavelength in height.

If you just must have a answer, run it N/S. As yet you have to say what you want to do, (i.e. DX, ragchew, local hop, WAS nets).

Or just ground both ends and when you figure out what is wrong you will have questions one would expect from a general class Ham operator.

This is about experimentation, NOT someone giving you answers you should be able to figure out.

Hate if I hurt your feelings.

6534. Re: can you use an antenna tuner and an SWR meter?

Yahoo group: ham-antennas (2008)
Date: 2008-10-29 20:38:01 UTC
From: Rick
Topic: 6506 Message: 6534

If you want to make sure the antenna is setup properly, then you really don't need a tuner. If you setup the antenna right, the swr will be low without a tuner. If you want all band operation with one antenna then do away with the coax and use ladder line and the tuner and as long as the tuner will match it to the radio you will get out just fine ! BUt agin, if you are using a coax fed antenna then skip the tuner and adjust the antenna to resonance if you are worried about it being setup properly.
73
Rick
KC8AON

But isn't this what I'm looking for? I mean I need to know the VSWR of the coax/antenna (since I'm assuming the tuner will try to make the radio think it sees a good SWR ~1-1.5 even if I'm trying to tune a rock). What I really want to do is figure out if the antenna/coax system is setup correctly to radiate RF in the freq/band of interest.

SHARE, and I did if your read the entire post, not just the part you want to complain about.

BUT not give away. If we are to give it all away, why have classes? Lets just open it all up, like CB.

TEACH is a better thing to do. TEACH a person where to look, not GIVE away answers.

I know my TEACHERS did NOT give me the answers.

With books the GIVE the answers to the tests, were are we TEACHING?

TEACH in everything we do.

Also to keep a perspective on this, the guy was asking which way to put up a wire antenna. That is in anybody's book just about as basic as you can get.

How many wavelengths long will it be at the lowest frequency you want to
receive at? For example, if it is only 150' long then it is only a 1/4
wavelength at 80 meters. Not a true long wire. So signals will be
strongest broadside. It will have different lobe shapes as you go higher
in frequency, at at 28 MHz it might look like a cloverleaf.

The best way to tell is download a copy of EZnec by W7EL at
<http://eznec.com/> and run it. You can adjust the variables like wire
length and height to see what happens at different frequencies.

Does this help?

Lost the ball off a whip tip recently and replaced it with a teardrop shaped

piece of 2 part epoxy putty. I suggest that for a piano wire whip also.The
one I tried worked well and might save an eye.(G)

Steve,

Thanks for the reply. Actually, I'm not an amateur radio operator (I hope that's ok) but have found this group helpful in determining what type of antenna I should be considering.

I have been a scanner listener for many years (civil & mil air) and have recently ventured into hf with the purchase of an R75. HF is a new experience for me so I'm still learning. I'm currently using just a 200' random wire but have been working on constructing an antenna based on a design I found from "Webmaster Hamuniverse.com....N4UJW" using a formula to calculate wire length for a half-wave antenna. I have been using his basic design but have customized my wire lengths to coincide with freq ranges used by civil & mil air since that's all I will be monitoring. For instance, one group of these freqs range from 10780kHz to 11271kHz. I have averaged the freqs in this particular range and the average is 11158kHz. Based on this and his formula, I calculate the wire for this range should be 41.9 feet long. I have done this with several of the freq ranges and plan a wire for each range (seven total). Based on my lot size, it looks like the lowest freq ranges I can go to is approx 6700kHz (a wire length of approx 69.5 feet. Any longer than that and I can't string it in a straight line and end up near some overhead power lines. I hope my logic in this design is somewhat correct. If I've done something wrong with the design, I welcome any feedback.

I hope to have assembly completed this weekend and begin installation. The highest I can install it will be approx 20-25 feet. That's what generated my original post.

Your feedback will be appreciated.

I applaud your decision to avoid the power lines. Hate to hear of your
demise.

You will probably see a pattern like two hot dogs back to back, only
fatter. The polarity might also change going from horizontal broadside
to vertically off the ends. So you might notice some really weird
propagation where you won't here things you might think you should.

I would just do it, and see what happens. Then let us know how it worked
out. You can always move things since nothing is being put in cement, is

it? You'll just need to let the kids and wife know where you string things up so no one hangs themselves on it.

Antenna arrangement is always fun. It is where you can experiment and see what improvements you can make.

Remember a few emails ago I mentioned EZnec software? It is fun to play with that also and see if what you build actually does what the software says it will do.

Steve/WM5Z

6547. What does the group think???

From: Ken K6KAW
Topic: 6547 Message: 6547

Greetings from K6KAW....

I have decided on an antenna for my place. Now just a reminder I live
in an apartment in CM87. I am on the second deck and I have access to the roof.
I hope the landlord will not cry foul when I ask to put this one up.

I like the " Alpha Delta DX-EE ". At only 40' long I think I can do it.
Has any one use one? What kinda reports? It covers the bands I would
like to get started on. The only thing is it is fairly narrow at only 50 - 60 kHz
spread.

I will leave the rest to the group to ponder. I hope to get a Yeasu FT-857D
but if I have to I will settle on the FT-817D. After all " Money Talks "

73 K6KAW

6550. Short 20M

Yahoo group: ham-antennas (2008)
Date: 2008-10-29 23:45:08 UTC
From: Richard Schmuke
Topic: 6550 Message: 6550

I made up a wide band □cage□ vertical, I had to trim it short when making it to get the resonate frequency where I wanted it. We finally had a chigger killing frost so I mounted it with the feed point up about 21□ today. 12 radials length for 14.1 MHz , with monofilament line so they were about 45 degrees, vertical is 4.25 square with 8 wires. When I checked it the frequency came in about 15.5 Mhz. I returned it to the building set up with feed point about 6 ft off the ground and radials spread around , this time it checks about 14.1 MHz. If I put tension on the radials to bring the more 90 degrees to the antenna the resonate frequency goes up , droop the radials it goes down. It is feed with RG8X , 5 wrap choke around the mast just under the feed point. When mounted at 21□ the wind blows and the frequency moves.

Any ideas?????

I made up a wide band ?cage? vertical, I had to trim it short when making
it
to get the resonate frequency where I wanted it. We finally had a chigger
killing frost so I mounted it with the feed point up about 21? today. 12
radials length for 14.1 MHz , with monofilament line so they were about 45
degrees, vertical is 4.25 square with 8 wires. When I checked it the
frequency came in about 15.5 Mhz. I returned it to the building set up
with
feed point about 6 ft off the ground and radials spread around , this time
it checks about 14.1 MHz. If I put tension on the radials to bring the
more
90 degrees to the antenna the resonate frequency goes up , droop the
radials
it goes down. It is feed with RG8X , 5 wrap choke around the mast just
under
the feed point. When mounted at 21? the wind blows and the frequency
moves.

Any ideas?????

That much?? from 14.1 to 15.5MHZ . The SWR goes to high on 20m to work well
that way.

I agree with that point that it should be done at working height but why does the resonate frequency change when the radials move around with the wind??

I tried make it lower because it is heavy to raise and lower the steel pipe it is on with my bad back.

Hi Ted et al,

Thanx for the info. The antenna looks like it is almost new. The coils remain in their protective cardboard sleeves.

I think that I am going to make a sleeve for the post with some aluminum tubing. I'll cut a slit and secure with clamptite wire (http://www.clamptitetools.com/) I'll use some appropriate nuts for the 3/8 x 24 thread.

This project if for a cliff dwelling friend and may mean the difference for him to get on the air or not. Again thanx to all for the tips.

73,
Mark

> Mark,
> I had on of those in the early 80's. The whip was a replacement auto whip that would go over a snapped auto antenna stub securing with set screws. It was designed for a 5/8 or 1/4 inch rod and was about 4' long. Loading coils were Miniductor stock for 20,15 and 10 meters and a large coil wound on a fiberglass form with magnet wire for 40. All slipped over the lexan rod. A marked 32 foot cpoise wire was supplied. You mounted the antenna and adjusted the counterpoise for lowest swr. It didn't work more than it did. B&W came out with a single coil on a pvc form that was clipped and marketed as the AP10.

6562. hey guys take a look at this idea

Yahoo group: ham-antennas (2008)
Date: 2008-10-30 13:53:17 UTC
From: dennisissure
Topic: 6562 Message: 6562

Single story brick construction duplex apartment home.

The gutters are 63' horizontal each side
The downspouts are 10' each corner both sides
Total gutter material each side is 83'
It wouold take a jumper wire 23' long to tie the far side ends together
giving me a total material length of 189'.

or

I could feed each half like a dipole! A gutter dipole with a max height of 15'
and the ends of the downspouts at 6-8" off the ground.

Currently the tree on the left has a 139 foot wire ((14 gauge insulated stranded copper wire)
that goes from the ground 12 degrees tapered away from the tree and up to the top where it is 90' vertical and then the reaminder of 49' goes horizontally to an insulator and then the
nylon cordis stretched to the top of the tree on the right and dropped down and tied off. This is fed against a radial system and currently a single 139' counterpoise wire but I am having a few issues with it right now .. The main purpose of that antenna is to get on 40-80 and 160. I am trying to put together a RF choke at the input of the antenna and another
choke where the coax enters the home.

Would appreciate any help in the modeling or resurecting of these two antennas. If I get the RF issues resolved on the vertical I will be a happy topband camper.

73s for now and if anyone wants to call me and discuss the antennas please do so at 803-389-9366. This is my cell phone and I am usually available unless I'm enroute to the VA for treatment or examinations of sorts. OH and yes, if anyone know where I might obtain used RG8x or RG58 coax in the SC area and also 300 ohm twin lead or used 450 ohm ladder line thata is not too costly; I'd appreciate a heads up. it's not easy trying to start over; but it is sure is interesting.

I just built a similar vertical for 40 but my "A Frame support" is only 36 ft so it's basically ground mounted. Next I'm not using radials I'm using a spiral counterpoise that seams to be working well. So I haven't had the same problem with the wind that you have. I did have to put a choke at the feed point be cause of RF in the shack. What kind of 2:1 band width are you getting on your vertical I was very surprised at what I was getting on 40 (270 khz) I'm using 8 #22 wires and the cage is 12" in diameter. it's 33' long but I had to add some inductance at the feed point to bring it down to where I wanted it it started out resonant above the band. I believe that the capacitance of the wires electrically shortened the antenna.

I would use some sort of balanced fee line and feed the two sections like a dipole you should be able to tune all the bands. My main antenna is a 150' dipole feed with 450 ohm ladder line and I use it on 6 - 160 the only problem would be at that height for most bands it would be a cloud burner but at least you would be on the air. I would also make sure that all of the gutter sections are bonded togather in each leg.

6565. RE: [ham-antennas] Short 20M

Yahoo group: ham-antennas (2008)
Date: 2008-10-30 15:34:11 UTC
From: Richard Schmuke
Topic: 6550 Message: 6565

Danny , thanks for the reply. I can cover the 20M band with 1.5:1. I may have goofed when I made it because I trimmed the length of the cage to get the resonate frequency where I wanted it. This AM it is on a stand in the middle of the yard. Feed point 6 ft high, with the 12 radials drooping down, then spread across the ground. The radials do not go straight to the ground but form a catenary curve in their natural state. If I apply tension to them the resonate frequency goes up to about 14 Mhz. Place the radials as straight down (6ft) to the ground then fan out and it goes to about 13 Mhz. I have a spread of 1.75 MHZ for a 2:1 with my MFJ259. I may place it back on my 21ft pole and adjust the radials to control the frequency.
There is a definite shorting effect with the cage , I am looking for a PSK31 and phone antenna with a low SWR.

Subject: Re: [ham-antennas] Short 20M

I just built a similar vertical for 40 but my "A Frame support" is only 36 ft so it's basically ground mounted. Next I'm not using radials I'm using a spiral counterpoise that seams to be working well. So I haven't had the same problem with the wind that you have. I did have to put a choke at the feed point be cause of RF in the shack. What kind of 2:1 band width are you getting on your vertical I was very surprised at what I was getting on 40 (270 khz) I'm using 8 #22 wires and the cage is 12" in diameter. it's 33' long but I had to add some inductance at the feed point to bring it down to where I wanted it it started out resonant above the band. I believe that the capacitance of the wires electrically shortened the antenna.

Subject: [ham-antennas] Short 20M

I made up a wide band □cage□ vertical, I had to trim it short when making it to get the resonate frequency where I wanted it. We finally had a chigger killing frost so I mounted it with the feed point up about 21□ today. 12 radials length for 14.1 MHz , with monofilament line so they were about 45

degrees, vertical is 4.25 square with 8 wires. When I checked it the frequency came in about 15.5 Mhz. I returned it to the building set up with feed point about 6 ft off the ground and radials spread around , this time it checks about 14.1 MHz. If I put tension on the radials to bring the more 90 degrees to the antenna the resonate frequency goes up , droop the radials it goes down. It is feed with RG8X , 5 wrap choke around the mast just under the feed point. When mounted at 21☐ the wind blows and the frequency moves.

Any ideas?????

6566. Wire and Cable for Sale - Selling Home and it all must go.

Yahoo group: ham-antennas (2008)
Date: 2008-10-30 17:23:31 UTC
From: denisnh
Topic: 6566 Message: 6566

Hi All. Due to a series of personal setbacks, I am forced to sell my home. I am currently moving all my stuff out and am selling off as much as I can.

I have several rolls of new, unused wire. Some of it is industrial surplus, but it is all in new condition. I did NOT get this stuff free, so I'll sell it for the lowest prices I can. The price per foot is still much lower than anything surplus or otherwise you'll find anywhere. If you do find the following items for less money, please let me know. I have just posted this wire on Craig's List under the links below.

Right now I have two types of wire for sale:

1) 12 ga. PVC jacketed copper stranded, ideal for just about any type of wire antenna.
http://boston.craigslist.org/nwb/mat/893796223.html

2) Military spec RG-58/U, 50 ohm coaxial cable also in new condition, never used.
http://boston.craigslist.org/nwb/mat/897230310.html

Shipping is available for those who don't live in the area, or it can be picked up in Billerica, MA.

Thanks,
Denis

Y'know, there's one thing that I did not see, especially at the building entrance. The station lightning ground.

I'm sure that the tower is grounded, at least through the foundation but I hope that the guy who threw all that cash into such an aggressive system didn't skimp on the most important part of the project.

6572. RE: [ham-antennas] Temporary Tower Guys

Yahoo group: ham-antennas (2008)
Date: 2008-10-31 03:25:03 UTC
From: Dave
Topic: 6572 Message: 6572

Dear Group:

Need some advice. I have a Rohn 45 tower, 70' tall, guyed in two places, 35' and 70'. I want to raise an antenna - full size 3 element 30 meter - this Saturday and want to take it horizontally, straight up the tower. This will require releasing one of the guy wires at 35', until the antenna passes, and then again at 70', until the antenna passes reattaching each as the antenna passes. I really believe that as I release one of the guys, I should temporarily guy under the antenna being raised, especialyl at the 70' level. My question is: Can this temporary guy be rope (5/8") brought tight, or should it be guy wire (3/16")? And, since I'll be simply stringing this temporary guy around a tower leg and cross strut, how tight should, or can this guy be?

Thanks in advance.

Dave, W8QW

Have a gutter repairman splilt it in the middle, each side would then
be a separate gutter section
with its own downspout, and you would have a dipole to
feed with 450 twin lead and a tuner. cheap antenna, probably work FB.

About 1967 I lived in an apartment on the 2nd floor, frame
construction,vinyl siding,
had gutter running length of unit (about 150'), I used a tuner and a wire clip
lead to feed the gutter through/from my front door, worked very well.
(simple 'L' tuner, one cap, one inductor). Rig then was Eico 753.

6576. 75 Ohm Coax

Yahoo group: ham-antennas (2008)
Date: 2008-10-31 11:39:41 UTC
From: Callum M0MCX
Topic: 5916 Message: 6576

Allan,

I promised some time ago to track down the low(ish) loss coax my engineer gave to me, it's WEBRO WF100 LSF, about 6mm. Much better than contractor's coax. Do a google search and you'll find it.

Sorry to be so late in this one.

Regards,

Callum McCormick

Allan,

Try WF-165. It's same style as RG213 but 75 ohm.

Nevada stock it.

See http://www.nevadaradio.co.uk/acatalog/cable-wf1651.html

I'm doing exactly the same as you, replacing my cheap crappy stuff with WF-165 to cut down on home-made interference.

Cheers,

Callum McCormick

Subject: [ham-antennas] OT - 75 Ohm Coax

Slightly off topic....
I want to re-wire my TV leads with better standard 75 ohm cable. However all
teh UK sources I can find have only upto 60% braid coverage (albeit with
foil as well).

Is there a source of 80%+ braid covered 75 cable available?
If not is 60% with foil any good by comparison?
Can RG58A/U be used as an alternative or will the impedance mismatch negate
any gain

thanks

Yea, thanks for a NEW topic.

You can do a couple of things. One would be to build it with traps. Hi C
traps for 10 will leave you with enough length for the next band. One of
the problems with Hi L traps is they shorten the antenna to much.

Another idea would be to model your antenna after a commercial version.

Let us know what you do. Others here want to know.

Steve/WM5Z

I would use one of the antenna simulator programs to play with.

From: Mike Check
Topic: 6602 Message: 6614

I had a Butternut Butterfly up several years ago that worked pretty good. MY OPINION is that they are not built very solid, but it did work pretty good. It will actually do 10-20. It is a 2 element goofy "boxkite" looking thing, with 17m covered by one element as a rotatable dipole. For 12m, you point it in the opposite direction. It worked very good on 12 and 10, okay on 15, 17 and 20.

6615. Center Insulator Balun Question

Yahoo group: ham-antennas (2008)
Date: 2008-11-02 01:01:01 UTC
From: Jonathan Helis KB5IAV
Topic: 6615 Message: 6615

I bought a balun/center insulator from Wireman for an OCF dipole experiment I want to build.

I've never used one of these before since most of the antennas I've built were either single wire or twinlead fed and need some tips.

I need to know what is the best way to put it up. I'm using #12 insulated wire for my antenna(got a spool of it cheap recently), and am trying to figure out how to attach it to the insulator. Not sure if I should simply attach it under the nuts that are on each side, or if I sould strip off alot of the insulation and use the two braids that are already attached to it.

I know this is probably a silly question to ask, but I've never used one of these before and need to know a good way to attach it so it stays attached. Also, want to get the group back on the topic of antennas.

Thanks.

From: Its from KE4VYN
Topic: 6615 Message: 6620

What I do is take a insulator, one of those cigar-type ones and connect the wires from the balun THRU the ends of the insulator. Securing the wire so it wont pull thru and then on to each insulator at the ends of the wire.

So the insulator is directly above the balun and the balun, 'hangs' from the insulator by the antenna leads. Therefore putting all of the end pull strain on the insulator and not the balun.

The beta (also called hairpin) matching section will require insulating the driven element halves from the boom. Hy-Gain used it, and M2 says they use it. I've never tried it.

I have a Cushcraft A3S that uses a simple dipole feed. It has reasonable bandwidth (under 2:1). The worst-case is 20m, due to loading. This will be the case with any trapped antenna.

In the early 70s, I put a Gotham 2-el 15m yagi up. Their instructions for making a gamma match left a lot to be desired, and I wound up building my own (from info in the ARRL Handbook). VSWR was about 1.2:1 at the band edges. The antenna later became 3 elements on a longer boom, with a remotely-tuned gamma match tuning capacitor. Even tho it was up only 38', it was a real DX magnet.

Hi Jonathan,

I pass the antenna wire thru the eyehooks on the balun/insulator and wind it back on itself a few turns. I then use appropriately-sized split-bolt connectors to connect the pigtail on the balun to the antenna wire. Split-bolt connectors (http://images.orgill.com/200x200/6174270.jpg) can be found in the electrical supply section of your favorite home improvement box store. No soldering required!

I'm curious if the wire you'll be using is hard-drawn. If not, expect some stretch (and decreased resonant frequency) over time. My first 40m dipole was made from 14ga solid soft-drawn. The resonant

frequency kept dropping, until the wire broke.

Brian
There are several alternatives. At one time my 4 element 20 meter monobander was fed with an omega match. Easier to tune than a gamma match. When I redesigned it as a modern 5 element design I split the driven element and fed it with a quarter wave of 37.5 ohm through a 1:1 balun with 75 ohm leading to the rig. It has very good bandwidth and swr characteristics but it is, of course, set up only for 20 meters. The choice of 37.5 ohm was based on the geometric mean of the input impedance and the transmission line. That required shortening the driven element to take out the capacitive reactance.

A folded dipole with a delta feed in my experience. Only thing tricky is making the folded dipole. The Delta feed likes a balun or balanced line feeder. The folded dipole impedance is usually 4 times what a straight dipole would exhibit. So, if the dipole would normally have an impedance of 35 ohms, then you would see a 140 ohm load. This is convenient as a delta likes to transform from a low impedance to a higher value.

The folded dipole does need to be split, but the split can occur where it is not against the mast. But, you will need to have access to a conduit bender. Several years ago I built one for 144 through 148 MHz. The SWR was less than 1.3:1 at each end, with the center of band at 145.8 MHz. I used copper tubing for the element. The Director and reflectors were aluminum. The spacing between the loops was .05 wavelength. With 1 reflector and 3 directors I realized a F/B of 20dB, a gain of 7 dB and at center of band the SWR was less than 1.05:1

Thanks for the tip. I'm using #12 stranded wire. I bought a huge spool of it on Ebay that was actually cheaper than I could get it anywhere else so I could have alot of wire to use for antenna construction/experimenting.

I'll look in to those connectors too and see what I can find.

Thanks.

Topic: 6623 Message: 6639

No, or at least all the M2 antennas I have the driven element is not
insulated, and or split., it's just like if you were to gamma match it.

6647. G5RV Configurations

Yahoo group: ham-antennas (2008)
Date: 2008-11-03 00:36:50 UTC
From: Scott Laughlin
Topic: 6647 Message: 6647

A few weeks ago someone was interested in what configurations a G5RV would tolerate and still provide gain. I located my TechNote #124d, Building and Installing G5RV Antennas for Effective Multiband Performance...by AntennasWest 1999.

On page 13 are Special Purpose configurations:

Inverted U
Sloper/Vertical/Inverted L
Bi-Square/Delta
Shotgun Square/Delta
Open Horizontal Loop

There are limited details on each configuration. If anyone whats more information I'll gladly share whats here.

72 de Scott/n7net/qrp

Hello Scot,

at least I will be happy to see it. I plan to install a multiband antenna
for a long time, and G5RV is an option.

Jon,

Check the current issue of the *QRP Quarterly*, page 6. This may not be what you're looking for, but it's interesting just the same. If you don't have access to this publication you might consider going to:

<www.qrparci.org>

Hi Jon,

Can't help you much but somethings to consider. There are software analyzers and hardware analyzers plus lab grade or good enough. Personally I have the MFJ 259b which is 1.8-174mhz. It works well for me. (Good enough). MFJ also have a version that does the 70cm band. From my looking around good enough meters run $600 or less and lab quality goes up from there. Hope that helps some.

Hi Jon,

I use an MFJ-269 myself. It does a reasonably good job. I am able to find the resonant point of any antenna I use from 1.8 through 440 MHz. I can see the SWR, the "true" impedance and see if there is any reactance. It will do just about anything you might need an analyzer to do. It won't sweep a band and plot on a computer screen, but otherwise it is portable enough to go up on a tower if needed.

Thank you Sigi, but I have only 35m.
Now I use a 2x20m dipole fed with coax, which is ok on 80 an 40m.That's all.
I intend to replace coax with ladderline, but due to a lot of buildings,
metal structure, etc I'm not sure if it is a good idea.
Thanks anyway!

>>loop antenna around the top of the roof of your house

Hi,

Well it would be fun to hear if it works out of not. Just a few issues I can think of. Interaction with the metal gutters if its to close, stay away from the power lines and possible RFI in the house. I never tried a loop around the house but I did try a dipole for 20m. The only issue I had was it seemed to pick up more noise from the house then being strung on two poles with a fence in the middle.

6664. AW: [ham-antennas] LOOP antenna - was: G5RV Configurations

Yahoo group: ham-antennas (2008)
Date: 2008-11-04 12:01:48 UTC
From: Siegfried Jackstien
Topic: 6650 Message: 6664

dear allan
surely it is possible to build a smaller version for 80m and up
my version is for all bands cause i have enough room ....
it is a 168m delta 12-15m over ground for the two lowest band i use 2
different length of feeding line
i have abt 18m from my shack to the feeding point over my roof and for some
bands i ad another lenght of abt 20m (it is spanned under the roof in a
circle)
both ends of the added lenght end in the shack and i simply switch it in
between with banana plugs
i made an excel sheet for my notes cause it took me 3-4 days with cut and
try cut and try .....
the balun is very simple
i had a selfmade 1:4 in my tuner and found out that swr was low on several
bands with this antenna ... just wanted to see what happens when it is a 1:9
three wires over a amidon 200a red iron powder core
for easy connecting and explaining i say 1 wire red 1 wire brown and 1 wire
black
each about 1m long
make connection points in the middle of red and brown
that is 50 ohms input (red is hot brown is gnd)
take that three wires parallel and turn it 5 times over the upper half of
the core
after that make the rest of the wires on the lower part of the core in 5
turns
now connect on the opposide of the input the wire low red with upper brown
upper black with lower brown
ready with balun
how connect it?
connection points for input explained earlier (upper part of text)
high red is one point for the feeder
low black ist the other point for the feeder
electrically you have 10 turns on the input and 30 for the output with gnd
in the middle
1:3 turn ratio is 1:9 transformer
if you would cut the core it would look like this
(every c is a turn over the core and the "o" s are solder joints

```
c--------O 450 Ohm output
c red
c 5turns
c upper core half
c-
O-------O < 50 Ohm input hot
c-
```

```
c red
c 5turns
c lower core half
c-
O solder joint
c-
c brown
c 5turns
c upper core half
c-
O-------O < 50 Ohm gnd screen
c-
c brown
c 5turns
c lower core half
c-
O solder joint
c-
c black
c 5turns
c upper core half
c
!
c black
c 5turns
c lower core half
c
c--------O 450 Ohm output
```

i hope everybody understood my explanation :-)

i will upload the excelfile and everybody will see that there are MANY resonance points
160, 80, 60!, 40, 20, and up
the swr is <3 on all bands and on some bands it is exactly 1
so most of the time you need NO tuner
on the higher bands swr is not 1:1 but is so low that losts in the tuner are very low
i didn´t try this antenna as a shorter version (for 80 and up) but i think it will work like the same
on the 2 lower bands the feeding impedance is low cause the antenna is only 12-15m high in the air but transformed the impedance over quarterwave lenght to abt 450 ohms
then the balun brings it down to 50 ohms
on 40 the 2 different lenght are half or fullwave so no transforming but the impedance is
abt 400 ohms in the feeding point and the ladderline is in a matched situation
on the higher bands the ladderline is "almost matched" so it is the same like on 40
not exactly but swr is very low anywhere over 14 megs.... (try on yourself)

if i had a network analyzer i would upload pictures from the measurements
but i have none :-(
maybe you can open the 80m loop with a switch to have a (folded) dipole for
160
but pay attention on the lenght of the feeding line ....
that is the tricky thing on this multiband antenna

oh what a very big text hi hi
but i think it will help some others to understand this special antenna :-)

for a long time, and G5RV is an option.

dear adi
2x20 is okay for 80m but for 40 it is a fullwave dipole so impedance is very high
swr is high on the coax and so will the losses be high
if you have the room for a dipole you almost have room for a loop
just close your dipole with another lenght of wire and you have more wire in the air
you can open the loop with a switch to have a folded dipole for 160

Betreff: Re: [ham-antennas] G5RV Configurations

Thank you Sigi, but I have only 35m.
Now I use a 2x20m dipole fed with coax, which is ok on 80 an 40m.That's all.
I intend to replace coax with ladderline, but due to a lot of buildings, metal structure, etc I'm not sure if it is a good idea.
Thanks anyway!

Dear Sigi,

can you send a picture or a link with your antenna? I'm not sure if I
figured out the right way.
Thank you!

oh adi you are online now!!!
it is very simple
horizontal delta 168m from feeding point over the roof of my house
abt 60m in a tree at the end of my garden then 70m to a 10m mast and then
40m back to the feeding point (you see this is 170m hi hi)
the exact lenght is abt 168m i made it longer and then cut ant try cut and
try
like you always should with buildind an antenna
cutting is easier as soldering another little wire in between :-)
from feeding point abt 18-20m to the shack and another 20m lenght of the
feedingline is under the roof of my house in a circle
i hope you understood now

6668. Re: [ham-antennas] G5RV Configurations

Yahoo group: ham-antennas (2008)
Date: 2008-11-04 13:51:18 UTC
From: Bill
Topic: 6647 Message: 6668

Adi T
ake a look at the so-called "Super Loop." Mine is about 98 feet across the top (29.88 meters) with about 62 feet (18.9 meters) for each of the lines from the ends to the 4:1 balun at the apex. (It is an inverted triangle.) The center of the horizontal part is divided in the middle like a dipole and a 1/4 wave stub of 450 ohm ladder line cut for 40 meters and closed on the far end is attached. The 4:1 balun is fed with 52 ohm coax. The antenna acts like a bi-square on 40 meters and a full wave loop on 80 meters. Mine was tested at the feedpoint and exhibited 200+j0 before installation of the balun on 40 meters. The Super Loop gives good gain on 40 meters and acts well on 80. Although I do not use it on 20 is has good references for that band too. I have used it successfully on the WARC bands. (I have a 5 element monobander on 20 and a tribander for 20 15 and 10 so I don't use it on those bands) Check out the design on WH2T's web site by googling the WH2T Mini Super Loop. Mine is modified from that using eznec but is very similar. The advantage if you have the height available is that it does not take as much horizontal room as a dipole cut for 80 meters.

Sigi

Thanks for your very full reply and XLS. I shall have a proper read at the weekend and see if I can transpose it to a smaller loop for trials here

thank you

Subject: AW: [ham-antennas] LOOP antenna - was: G5RV Configurations

dear allan
surely it is possible to build a smaller version for 80m and up
my version is for all bands cause i have enough room ....
it is a 168m delta 12-15m over ground for the two lowest band i use 2 different length of feeding line
i have abt 18m from my shack to the feeding point over my roof and for some bands i ad another lenght of abt 20m (it is spanned under the roof in a circle)
both ends of the added lenght end in the shack and i simply switch it in between with banana plugs
i made an excel sheet for my notes cause it took me 3-4 days with cut and try cut and try .....
the balun is very simple
i had a selfmade 1:4 in my tuner and found out that swr was low on several bands with this antenna ... just wanted to see what happens when it is a 1:9
three wires over a amidon 200a red iron powder core
for easy connecting and explaining i say 1 wire red 1 wire brown and 1 wire black
each about 1m long
make connection points in the middle of red and brown
that is 50 ohms input (red is hot brown is gnd)
take that three wires parallel and turn it 5 times over the upper half of the core
after that make the rest of the wires on the lower part of the core in 5 turns
now connect on the opposide of the input the wire low red with upper brown
upper black with lower brown
ready with balun
how connect it?
connection points for input explained earlier (upper part of text)
high red is one point for the feeder

low black ist the other point for the feeder
electrically you have 10 turns on the input and 30 for the output with gnd in the middle
1:3 turn ratio is 1:9 transformer
if you would cut the core it would look like this
(every c is a turn over the core and the "o" s are solder joints

```
c--------O 450 Ohm output
c red
c 5turns
c upper core half
c-
O-------O < 50 Ohm input hot
c-
c red
c 5turns
c lower core half
c-
O solder joint
c-
c brown
c 5turns
c upper core half
c-
O-------O < 50 Ohm gnd screen
c-
c brown
c 5turns
c lower core half
c-
O solder joint
c-
c black
c 5turns
c upper core half
c
!
c black
c 5turns
c lower core half
c
c--------O 450 Ohm output
```

i hope everybody understood my explanation :-)

i will upload the excelfile and everybody will see that there are MANY resonance points
160, 80, 60!, 40, 20, and up
the swr is <3 on all bands and on some bands it is exactly 1
so most of the time you need NO tuner
on the higher bands swr is not 1:1 but is so low that losts in the tuner are

very low
i didn´t try this antenna as a shorter version (for 80 and up) but i think
it will work like the same
on the 2 lower bands the feeding impedance is low cause the antenna is only
12-15m high in the air but transformed the impedance over quarterwave lenght
to abt 450 ohms
then the balun brings it down to 50 ohms
on 40 the 2 different lenght are half or fullwave so no transforming but the
impedance is
abt 400 ohms in the feeding point and the ladderline is in a matched
situation
on the higher bands the ladderline is "almost matched" so it is the same
like on 40
not exactly but swr is very low anywhere over 14 megs.... (try on yourself)
if i had a network analyzer i would upload pictures from the measurements
but i have none :-(
maybe you can open the 80m loop with a switch to have a (folded) dipole for
160
but pay attention on the lenght of the feeding line ....
that is the tricky thing on this multiband antenna

oh what a very big text hi hi
but i think it will help some others to understand this special antenna :-)

can something similar (read: smaller) be put together for 80 meters?

Is this just a loop of wire that joins to ladder line and then a 9:1 balun
to the tuner (or is the balun between feed/antenna?)

Have you got build instructions for the balun ?

useful to know as my small QTH also needs an aerial to get lower than 20m
band

dear adi
if you have enough room you should try my fullsized topband loop fed via ladderline and a 1:9 balun
this is really a multibandantenna that works everywhere with low swr and high gain
but its HUGE :-)

6670. 20 meter 3 el beam

Yahoo group: ham-antennas (2008)
Date: 2008-11-05 06:32:11 UTC
From: bushpilot169
Topic: 6670 Message: 6670

I have put togeather a 20 meter 3 el beam from the ARRL antenna hand book, thay called it an optimized beam, in the directions im to place a piece of pvc pipe 2.5" id aprox 76" long, and 12" behind the dir 1, Can someone tell me why? and if i was to leave it off will the beam perform poorly?

6671. AW: [ham-antennas] LOOP antenna - was: G5RV Configurations

From: Siegfried Jackstien
Topic: 6650 Message: 6671

dear allan
it would be nice if you make this smaller loop and share your measurements
with all the others
just make an excelsheet like i did
would be nice to see how this antenna works in a smaller version
but be sure to make the feedingline as quartewaves like i did
only with that you can use it with the 1:9 balun
as i said before you maybe can open the loop to make a folded dipole for 160
BUT the impedance on a low dipole is low so you have to use the long
feedingline to transform it in the
400-500 ohm range and then via the balun to abt 50 ohms

Sigi

Thanks for your very full reply and XLS. I shall have a proper read at the
weekend and see if I can transpose it to a smaller loop for trials here

thank you

Subject: AW: [ham-antennas] LOOP antenna - was: G5RV Configurations

dear allan
surely it is possible to build a smaller version for 80m and up
my version is for all bands cause i have enough room ....
it is a 168m delta 12-15m over ground for the two lowest band i use 2
different length of feeding line
i have abt 18m from my shack to the feeding point over my roof and for
some
bands i ad another lenght of abt 20m (it is spanned under the roof in a
circle)
both ends of the added lenght end in the shack and i simply switch it in
between with banana plugs

i made an excel sheet for my notes cause it took me 3-4 days with cut and try cut and try .....
the balun is very simple
i had a selfmade 1:4 in my tuner and found out that swr was low on several bands with this antenna ... just wanted to see what happens when it is a 1:9
three wires over a amidon 200a red iron powder core
for easy connecting and explaining i say 1 wire red 1 wire brown and 1 wire
black
each about 1m long
make connection points in the middle of red and brown
that is 50 ohms input (red is hot brown is gnd)
take that three wires parallel and turn it 5 times over the upper half of the core
after that make the rest of the wires on the lower part of the core in 5 turns
now connect on the opposide of the input the wire low red with upper brown
upper black with lower brown
ready with balun
how connect it?
connection points for input explained earlier (upper part of text)
high red is one point for the feeder
low black ist the other point for the feeder
electrically you have 10 turns on the input and 30 for the output with gnd in the middle
1:3 turn ratio is 1:9 transformer
if you would cut the core it would look like this
(every c is a turn over the core and the "o" s are solder joints

```
c--------O 450 Ohm output
c red
c 5turns
c upper core half
c-
O-------O < 50 Ohm input hot
c-
c red
c 5turns
c lower core half
c-
O solder joint
c-
c brown
c 5turns
c upper core half
c-
O-------O < 50 Ohm gnd screen
c-
c brown
```

```
c 5turns
c lower core half
c-
O solder joint
c-
c black
c 5turns
c upper core half
c
!
c black
c 5turns
c lower core half
c
c--------O 450 Ohm output
```

i hope everybody understood my explanation :-)

i will upload the excelfile and everybody will see that there are MANY resonance points
160, 80, 60!, 40, 20, and up
the swr is <3 on all bands and on some bands it is exactly 1
so most of the time you need NO tuner
on the higher bands swr is not 1:1 but is so low that losts in the tuner are
very low
i didn´t try this antenna as a shorter version (for 80 and up) but i think it will work like the same
on the 2 lower bands the feeding impedance is low cause the antenna is only
12-15m high in the air but transformed the impedance over quarterwave lenght
to abt 450 ohms
then the balun brings it down to 50 ohms
on 40 the 2 different lenght are half or fullwave so no transforming but the
impedance is
abt 400 ohms in the feeding point and the ladderline is in a matched situation
on the higher bands the ladderline is "almost matched" so it is the same like on 40
not exactly but swr is very low anywhere over 14 megs.... (try on yourself)
if i had a network analyzer i would upload pictures from the measurements but i have none :-(
maybe you can open the 80m loop with a switch to have a (folded) dipole for
160
but pay attention on the lenght of the feeding line ....
that is the tricky thing on this multiband antenna

oh what a very big text hi hi
but i think it will help some others to understand this special antenna
:-)

What page/section is this on? I'd like to look at the actual article
before speculating.

OK, I found it. In the article it is described as a "dummy" element to
compensate for torque due to wind loading:

> The last row in each variable tip column shows the
> length of one-half of the ?dummy element? torque compensator
> used to correct for uneven wind loading along
> the boom. This compensator is made from 2.5 inches OD
> PVC water pipe mounted to an element-to-boom plate like
> those used for each element.
In my book (the latest I believe) this is on page 11-16, bottom left,
next to the paragraph that starts "12-Meter Yagis"

So while it won't affect performance of the antenna, it will alter its
mechanical properties.

6675. G5RV Questions

Yahoo group: ham-antennas (2008)
Date: 2008-11-06 17:44:45 UTC
From: n0bn
Topic: 6675 Message: 6675

I have a summer job as a fire lookout on a mountaintop above timberline and have been using a G5RV the last 4 years for all band capability. I'd like some help in either optimally configuring this antenna or in deciding on a different one.

One end of the antenna is on the tower at about 35 feet and the other is on a mast at about 25 feet. The ladderline would reach all the way to the ground so I have been bending it at more or less 10 feet from the top and 10 feet off the ground: I bend it with a small guy line connected to the ground with the antenna end well padded.

As far as I can tell the mountaintop doesn't provide a very good earth ground but the mountain slopes down in all directions ... I have a 50 mile horizon.

I frequently get 40-50 mph winds and sometimes gusts as high at 60-80.

Several questions.
1) Is there an optimal distance from the antenna or earth to bend the ladder line considering I have to make such a bend?
2) Does it make much of a difference whether the antenna is horizontal to the local earth or horizontal to the horizon even if the latter means one end of the antenna is closer to the ground, especially considering it is very low to begin with?
3) Is there another reasonable alternative to the G5RV for multiband use which includes 80 M? (Maybe I could use a 40 M G5RV and add an NVIS 80 M dipole?)
4) Considering the current antenna is only 25-35 feet off the ground, would an full wave 80 M NVIS provide better local (300-500 mile) coverage? I would not be able to set this up horizontal to the horizon but only to the earth. (I don't want to put up several single band antennas but could put up a full wave 80 M dipole since that is the most critical band for most of my daily needs.)

I would appreciate any advice or suggestions (other than go read the ARRL Antenna Book(s) or model it myself)! Thanks!

Hi,

Next spring intertaining the notion of a few overnight bicycle trips and I'd like to do some CW while I'm resting these bones.

Here's the plan: I'll take along my MFJ-9040 (4 or 5 watts output) and a battery pack--8 D-cells. I have a 40-meter dipole pruned to work without a tuner, but trees aren't always where they need to be. I'd rather use a 40-meter ham stick tuned to about 7.055 mhz so I can leave the tuner at home.

Has anyone on this list ever done that? If so I'd be very interested in the details.

I appreciate your time

6684. PL-259 Installation

Yahoo group: ham-antennas (2008)
Date: 2008-11-07 17:22:38 UTC
From: Jon Maguire
Topic: 6684 Message: 6684

I have severe Rhumatoid Arthritis in my hands, so installing PL-259s has become impossible.
I remember seeing somewhere a tool that would assist in installing the connectors. Any information
on "easy" installation of PL-259s would be greatly appreciated. Thank you.

Something like this?
http://www.shopjavaco.com/page/shopjavaco/PROD/drop_cable_trimmers/UT
8000

Or do you mean putting the fitting on the cable?

Jon,

I have Cerebral Palsy, so I can relate to your frustration.
I can't hold the cable tight enough with my hands to prepare the
cable and put the fitting on.
I have been experimenting with a spark plug wire puller to hold the
cable / coax. You don't want to damage the jacket on the coax cable.
And a pair of channel locks type pliers with the jaws taped with
electrical type tape to not damage the fitting.
This is something you need to experiment with, to find what works
best for you. I hope this gives you some ideas.

From: w1ho
Topic: 6689 Message: 6689

antennas-hamDaniel,

Since you're using a tuner with the G5RV, why not consider an inverted L? Seems horizontal distance isn't too much problem for you, and you have the tower as the vertical support.

I highly recommend you check out LB Cebik's (SK) site,which is www.cebik.com. LB passed away this past spring, but his family and the folks at Antennex are keeping the site available. There is much info there on NVIS, G5RV, Inverted L and many other antennas. It requires a free registration to access the site.

Once you're on the main page, click on "Tales and Technicals", and then look at all the categories. You will find a whole category each on lower HF horizontal and lower HF vertical. I think you'll find much to help you decide.

73,

Howard

Daniel wrote:
G5RV Questions
Posted by: "n0bn" dghazen@... n0bn
Thu Nov 6, 2008 9:44 am (PST)
I have a summer job as a fire lookout on a mountaintop above timberline and have been using a G5RV the last 4 years for all band capability. I'd like some help in either optimally configuring this antenna or in deciding on a different one.

One end of the antenna is on the tower at about 35 feet and the other is on a mast at about 25 feet. The ladderline would reach all the way to the ground so I have been bending it at more or less 10 feet from the top and 10 feet off the ground: I bend it with a small guy line connected to the ground with the antenna end well padded.

As far as I can tell the mountaintop doesn't provide a very good earth ground but the mountain slopes down in all directions ... I have a 50 mile horizon.

I frequently get 40-50 mph winds and sometimes gusts as high at 60-80.

Several questions.
1) Is there an optimal distance from the antenna or earth to bend the ladder line considering I have to make such a bend?
2) Does it make much of a difference whether the antenna is horizontal to the local earth or horizontal to the horizon even if the latter means one end of the antenna is closer to the ground, especially considering it is very low to begin with?

3) Is there another reasonable alternative to the G5RV for multiband use which includes 80 M? (Maybe I could use a 40 M G5RV and add an NVIS 80 M dipole?)
4) Considering the current antenna is only 25-35 feet off the ground, would an full wave 80 M NVIS provide better local (300-500 mile) coverage? I would not be able to set this up horizontal to the horizon but only to the earth. (I don't want to put up several single band antennas but could put up a full wave 80 M dipole since that is the most critical band for most of my daily needs.)

I would appreciate any advice or suggestions (other than go read the ARRL Antenna Book(s) or model it myself)! Thanks!

Joe,

Most us in the UK use some self-amalgamating tape and wrap this around the connector. It goes like a fluid rubber that needs to be cut with a sharp knife to remove. Some folks spray the connector with a grease before fitting the tape. I've also heard of glue guns being used then electrical tape.

I've recently moved over to waterproof PL259 connectors that fit the same as N-Types but of a very high quality. In our money, they're nearly 10 UK Pounds each (15 dollars for you chaps). They're from SSB Electronics in Germany. Same company that makes that fantastic Ecoflex. I just bought 100 meters of coflex 15 and it's lovely stuff.

I have both the UT-8000 and the near identical DXE-UT-80 and both are OK as long as you have a stiff coax jacket material. It is useless with TIMES BuryFlex or similar where the jacket material is so soft it does twists within the tool and does not strip properly.

Joe,

I use silicon tape. You stretch it around whatever you are trying to seal. It fills in cracks and such and sort of melts to itself. When you are done it is really really water tight. If you want to remove it you can just cut it off like any other tape. The liquid products work but they are so messy.

HI, I just seen the video of the DXE-UT-80P but still don't understand what it does??? As you see the PL259 parts being being put onto the coax , and the coax has been prepared read for the DXE-UT-80P, so does it only screw the 259 onto the coax ?? as i have done that by hand every time, or is it a tool for people that have restricted use of the hands.

Jon,
Here is a good tutorial on installing crimp-on PL-259s;

http://www.bcdxc.org/pl259_crimp_on_connectors.htm

Also www.talleycom.com

has many crimper tools and the crimp-on PL-259 for both fat and
skinny coax.

The liquid rubber paints like dip it work great, as does coax seal, and some other things. Here is what I do, I take and wrap the connection with electrical tape leaving the bottom of the male connector uncovered to allow it to breath and let out humidity so it doesn't flow down the braid. Then I wrap with coax seal and , leave the lower end uncovered again, I have never had water trouble this way. I have a cell tower on my farm and the tower crew did the connections that way up top so I followed their example.

If you got it from a TV man it most likely will be 75 ohm. What type of radio are you going to hook up to, most can work with 75 ohm line , just a little bump in the matching , no special device needed.

It is most likely RG6. That is the most common used stuff now days.

I wouldn't worry about matching from 75 ohm to 50 ohm. You would have
more loss in the matching network than the 1.2:1 SWR will give you.

Paul,

I've not had much luck with the foil shield used on the coax you have, but maybe with the proper tools it will work for you. I don't know why couldn't make a balun with it.

I guess you are talking about the 300 ohm twin lead? It's harder to find these day. Call you local Ace Hardware Store. I bought some there about a year ago.

You can fabricate a pretty nice 2-meter j-pole from the twin lead. If you don't have the plans I can email them to you. Sometimes the VSWRs don't want to settle down when it's finished. If you have that problem you can make a decoupler with a six inch loop of the coax, three or four turn at the base of the antenna.

Welcome to amateur radio.

From: Scott Laughlin
Topic: 6707 Message: 6707

Hi,

I have a Small Wonder 20 that I've tuned to operate from 14.057 mhz to 14.095 mhz which covers the QRP frequency. The center frequency is 14.078 mhz. The antenna formula says that a wire 33' 3" resonate at that frequency. Will it resonate without a tuner?

I've already built a dipole that resonates at 14.078, but places to hang a dipole are not always convenient. So, I'm interested in doing the same thing with a long wire.

Tuners for dipoles are different than those for a long wire, so I'm wondering if I'm barking up the wrong tree, trying to resonate this wire without a tuner. Is a long wire considered a balanced load? I can't find a defination in the antenna book. Could I get away with wiring in a balun between the wire and the counterpoise and treating it as a twin lead?

I realize I need a countepoise or two. I haven't determined a length for those yet.

Paul

What do you want the 300 ohm line for ???? You are going to build what??
How long , I have some and it sure won☐t be $70

I have made J-Poles and Slim-Jims and made my own twin lead. The slim-jim is
just a wire on each side of a wooden stick. What are you trying to make??
I am sure someone here can help.

Don't worry about the RG 59 75 ohms is close enough you will only have theoretical miss match of 1.5:1 and in practice it will be more or less and you don't really need from a practical stand point to worry until it is around 3 or 4 to 1 any antenna tuner will fix it easily.

That must be some fine twin lead i buy mine for about 15 dollars per 100 feet

dear scott
if you wanna make a longwire for that qrg it is easy to build a stepup transformer
1:9 called "unun" not a balun
just take a "amidon red" core
take 3 wires in parallel
solder the beginnings end endings in that way that you have 10 windings in the input and 30 windings in the output
if you would cut the core it would look like this

```
c--------O 450 Ohm output > > > > to longwire

Definition of a long wire antenna is any antenna that is multiple wave lengths long at the lowest operating frequency. Most so called long wire antennas are really random wire antennas.

good TV type twinlead not like the garbage you find in some stores but Radio Shack and other higher quality 300 ohm will handle between 600 and 800 watts without to much trouble as long as the SWR is reasonable.

6714. Dual band dipoles

Yahoo group: ham-antennas (2008)
Date: 2008-11-10 18:26:31 UTC
From: Norm Blitch
Topic: 6714 Message: 6714

Is there any appreciable difference between the performance of a single-band wire dipole, compared to a two band fan style? I'm considering a 20 - 40 meter dipole sharing a common balun...

73 de Norm KE4GAH/AG

6715. Re: [ham-antennas] Dual band dipoles

Yahoo group: ham-antennas (2008)
Date: 2008-11-10 19:33:57 UTC
From: Steve/WM5Z
Topic: 6714 Message: 6715

Hi Norm,

I am presently using a Fan Dipole set up with 80/160 on the top, long leg. This is a trap dipole.

The next leg down is 40/75 trapped dipole.

The third leg down is a 60/30 meter dipole.

Everything is really happy, including the 75/80 band where there are two distinct dips each at just over 100KHz wide, one on the CW end, and the other on the phone end. 160 meters is 60 KHz wide, and that would be normal for the trapped length. 40 meters is 250 KHz wide and 30 meters is full band. All of this is with an SWR at minimum of less than 1.3:1 and at 3:1 when at the extremes. The center of the antenna is mounted at 40 feet, and the ends are at 20 feet up for the top leg, and at 10 feet for the bottom leg. On the 160/80/60/40 meter bands it is a cloud burner, but works really well for local nets. 30 meters starts to work like you would hope.

If I had the ability, I would love to put up a 66 foot tall vertical for working DX. As it is, I know it isn't the best for DX, but I still make some contacts.

When building it, I put a pulley on the top of the poles so I could raise and lower the antenna to tune it. I first set up the 160/80 meter legs for the very bottom of the bands. Then I dis-connected those legs and hung the 75/40 meter legs and tuned them for the lower end. I then re-connected the 160/80 legs, and found the antenna moved up just slightly. I left those right where they were and hung the 60/30 legs. I just cut to formula for the bottom of the bands, and they work just fine.

You may or may not have more interaction but I was very pleased as to how simple it came out being.

My overall lengths were 160' for the 160/80 meter bands and shorter for the other bands. Oh, and as a bonus, I also have 17, 15, 24 and 28.5 MHz bands, though the SWR is higher there, being near 2:1, but still useful.

I am feeding mine with 75 feet of LMR-400, with a homemade center insulator, no balun.

The only thing I have to say is make your 20m a little long and run it up to operating height and check SWR. I have one for 80/40/20/17/10 and I had the higher frequencies interacting with each other. It will depend on how close you wires are to each other.

From: Alan Cowan WA5ZKO
Topic: 6718 Message: 6718

Hi

I have dismantled a slightly damaged TA33 3 element beam and moved it to a new home location where it may be difficult to put up a beam.

I was 'considering' using one side of the driven element as a vertical by dismantling and feeding one leg of against a ground radial setup.

Does anyone know if this has been tried and if so, how successful was the attempt?

Steve,
WOW! That rig is WAY more complex than I envision; I'll just have the two wires, both un-trapped single banders...

I'm hoisting to the top of the chimney chase with a Harken double block rigged with a swivel to an eyebolt... Relating to your "cloud-burner" low-hangs, I was cautioned about the NVIS tendencies of low invert V's; I'm running a 20 meter wire dipole at 12' AGL center, and about 8' AGL at the ends, and getting 5-9's into Michigan, Wisconsin, and Missouri from North Florida. Europe sounds loud, but can't seem to "hear" <g>
Still undecided whether to go with an Alpha-Delta center connector setup, or a 1:1 coax balun homebrew...
73 de Norm KE4GAH/AG

Hi Norm,
I am presently using a Fan Dipole set up with 80/160 on the top, long leg. This is a trap dipole.
The next leg down is 40/75 trapped dipole.
The third leg down is a 60/30 meter dipole.
Everything is really happy, including the 75/80 band where there are two distinct dips each at just over 100KHz wide, one on the CW end, and the other on the phone end. 160 meters is 60 KHz wide, and that would be normal for the trapped length. 40 meters is 250 KHz wide and 30 meters is full band. All of this is with an SWR at minimum of less than 1.3:1 and at 3:1 when at the extremes. The center of the antenna is mounted at 40 feet, and the ends are at 20 feet up for the top leg, and at 10 feet for the bottom leg. On the 160/80/60/40 meter bands it is a cloud burner, but works really well for local nets. 30 meters starts to work like you would hope.
If I had the ability, I would love to put up a 66 foot tall vertical for working DX. As it is, I know it isn't the best for DX, but I still make some contacts.
When building it, I put a pulley on the top of the poles so I could raise and lower the antenna to tune it. I first set up the 160/80 meter legs for the very bottom of the bands. Then I dis-connected those legs and hung the 75/40 meter legs and tuned them for the lower end. I then re-connected the 160/80 legs, and found the antenna moved up just slightly. I left those right where they were and hung the 60/30 legs. I just cut to formula for the bottom of the bands, and they work just fine.
You may or may not have more interaction but I was very pleased as to how simple it came out being.
My overall lengths were 160' for the 160/80 meter bands and shorter for the other bands. Oh, and as a bonus, I also have 17, 15, 24 and 28.5 MHz bands, though the SWR is higher there, being near 2:1, but still useful.

I am feeding mine with 75 feet of LMR-400, with a homemade center insulator, no balun.
Steve/WM5Z

I would ask why you aren't just using it as a rotatable dipole? It should work well just by itself as such.

For field day I used a Cushcraft that is essentially just that, it's the same driven element they use for one of their beams, just sold as a dipole. Worked very well on a simple 20' mast tucked under the wheel of a van.

Alan,

Many years ago I read about a fellow on the East Coast who had setup similar to what you may be trying to do. He had two verticals that were on a turn table and phased so that the front one acted as a director. It looked out over the water and he simply turned it toward whomever he wanted to talk to.

You mentioned that a beam would be difficult. I used to chat in CW with a fellow in Long Beach, California. He lived in a neighborhood where antennas were forbidden. However, the spar of a sailboat was horse of a different color. That was a sign of progress.

As odd as it seems, his ham shack was in the boat and the antenna was a vertical taped to the spar. The last time we chatted the antenna police hadn't found that one yet.

"I was 'considering' using one side of the driven element as a vertical
by dismantling and feeding one leg of against a ground radial setup."

Alan:

Why not use both sides and elevate the antenna so a ground radial
setup is not needed. I have done this a few times with very good results.
I used a sidearm off the tower to mount it off the ground a few feet, but you
could use anything from a pole to a tree. This would eliminate the need and
hastle for placing a ground radial system around the vertical. The tuning
of the driven element changes slightly when vertical, but works very well.

Hi Steve/WM5Z.

Your 6-band, 3 trap dipole antenna farm sounds brilliant.

Any chance of a look at the traps you built, and what their resonance points were? A photograph of them would be fantastic too, if it's not too much trouble.

Thanks, es 73

Hi Norm, it's me again.

My point was that as complex as my antenna is, something as simple as yours should work for you as well. Hardest part is the center insulator decision. <grin>

Been there, done that w/ a Hy-Gain 203BA driven element. It worked
FB. I tried putting the other half up lambda/4 away from the first and
feeding +/- 90° from the first (cardioid pattern). Didn't work so well
but that was a long time ago, when my mistakes were more frequent.

Just thought I would share this with some of you who have not come across it. I Have one of these top antennas. I use it for portable NVIS work. I get 5/9+ all over the UK top to bottom. They are fairly easy to build but you have to wind it correct or you will find it wont tune up. It works on 80m to 10m and you can then roll it up throw it in a bag to store. I am using BT twin core phone wire thats the old stuff they used to string up in the streets pole to pole. The club is using 300 ohm ribbon feeder and some have used speaker / bell wire but I dont think they perform as good. Here is a link for those who wish to have a play.
http://www.gairney.plus.com/Radio/G5IJ_aerial.htm
There are plenty of links on the net. Have a play guys and let me know what ya think..... Its the T 200 toroid which takes some finding but you can buy off the net for about £6. Trust me its worth it. My mate has one set up in a small garden and it twists all over the place and works fine....

Bryan et al,
Thanks to all of you for the inputs and website info! Good feedback and information.

I may not have pointed out in my first post of the lack of room and no tower capabilities at my new place. I was looking for a 'quick fix' to get on the bands. I'm also looking at wire dipoles, but this seemed like an 'easy fix' for now.

The use of beam driven elements turned 90 deg makes sense if you can't go horizontal!

One more question to the group.

Once the element is mounted vertically, how many ground radials would be required? I've seen numbers in various sites ranging from 3 to more than 60 wires being radially laid out around the vertical.

Why the large range of radials needed?

thanks again!
Alan

Alan,

I wonder if you've considered an Isotron antenna? I've seen them in the HRO catalogs and often wondered if they really work or if they resonated all the house wiring. Until last week I'd not found any published literature other than that which is in the catalogs.

L.B. Cebik (sk) was evidently an authority on antennas and transmission lines and he publshed a number of books on these subjects. Included is a 470 page book on compact antennas, including the Isotron which you'll find at the website address I've included below.

Large range of radials is for efficiency less than 12 radials is very inefficient for ground mount at a few feet 3 or 4 in the air equal about 24 on the ground. I would use between 16 and 32 radials and make them at least 4 quarter waves and the rest at least 1/8 wave I have gotten decent results from antennas done that way.

I have heard of using a flag pole for a vertical antenna on several sites.
Even the "site police" should not object to "supporting our troops"

Kirk et al,

Thanks for the memory jog. I went on line and looked around the google search engine. Lot's of good info reports on radials, how many needed, why needed, etc.

There does seem to be a few reports that don't seem to think you need that many radials, but the vast majority of the other reports show nice charts/graphs on why you do need quite a few.

So, the plan is to take a look at mounting the TA33 driven element 10-20m with lot's of radials and then expand to 12/17m with the nifty info Sigi sent out.

Thanks again all
Alan

I'M SURE THE FOLLOWING NEWS RELEASE, THIS AFTERNOON, WILL BE OF
INTEREST TO MANY OF YOU....
********** ********* ********* ********* ********* ********* ********* ***
CQ COMMUNICATIONS ACQUIRES WORLDRADIO MAGAZINE

(Hicksville, NY and Sacramento, CA, November 12, 2008)
-- CQ Communications, Inc. has acquired WorldRadio magazine, CQ
Publisher Dick Ross, K2MGA and WorldRadio Publisher Armond Noble,
N6WR, announced jointly today. CQ, based in Hicksville, New York,
currently publishes CQ Amateur Radio, CQ VHF and Popular
Communications magazines.
WorldRadio, based in Sacramento, California, has been
published monthly since July, 1971, with a primary focus on the
human side of ham radio. CQ, a general-interest ham radio magazine
best known for its support of DXing and contesting, has been in
print since January, 1945.
Armond Noble, N6WR, Publisher of WorldRadio, said that
at the age of 74 the time had come for him to retire. "I wanted to
be sure that WorldRadio found a good home, and that our readers
would continue to be served by an independent voice in amateur
radio," Noble said.
CQ Publisher Dick Ross, K2MGA, said, "WorldRadio has
filled an important niche in our hobby for nearly four decades. We
welcome WorldRadio's readers to the CQ family, and we look forward
to meeting their needs for many years to come."
Current plans call for WorldRadio to continue to be
published online as part of the CQ family of magazines, with Editor
Nancy Kott, WZ8C, continuing in that position. WorldRadio
subscribers will also have their subscriptions transferred to CQ
magazine. Readers will be notified of details as plans are finalized.

6739. Experimenting and finding fact

Yahoo group: ham-antennas (2008)
Date: 2008-11-13 16:37:34 UTC
From: Dennis G. Peterson
Topic: 6739 Message: 6739

Hello, I am experimenting with an antenna that so far is simply phenominal. I am hearing every DX station posted on various DX clusters.

Now, they say; that "IF YOU CAN HEAR THEM---YOU CAN WORK THEM"
Almost true except for the fact that ONE must first have competitive power available. RIGHT?

My 100 watts surely isn't going to crack a pileup or topple KW stations.

Here is my scenario:

I have an inverted-L that slopes towards aPine Tree with a 12 degree slope. It goes up the tree until it reaches the top where it is 90 feet in the air and then goes horizontal for the remaining portion of the L. The total length of the wire is 138' 6" with the 38'6" portion horizontal. That yields a 90 foot vertical with a 48'6" horizontal portion.

This antenna's horizontal portion is oriented from EAST to WEST if that makes a difference. It is fed against a very modest radial field/counterpoise system. It is also fed with RG8x coax at the feed point.

The radial field consists of 5 or 6 electric fence wire pieces about 25 or 30 feet long. Held in place with metal lawn spikes that are 8-10" in length. There is a single counterpoise radial that lies on the ground somewhat underneath the top of the L. There is a second counterpoise that is only 105' in length and is doubled back with a 3' spacing of the wire.

I also tied ONE SIDE of the single story dwellings gutters and downspouts in to the radial field. THYE ONLY THING CONNECTED IN THIS RADIAL FIELD ARE THE RADIALS AND COUNTERPOISE WIRES TO WHICH THE COUNTER POISE WIRES ARE INSULATED AND THE OTHER RADIAL FIELD WIRES ARE BARE. THEY ARE CONNECTED TO THE SHIELD BRAID OF THE RG8X COAX.

The resonance regions of the antenna with respect to swr are as follows:
2.5:1----------1800
1.5:1----------1805 to 1820

2:1 SWR points are from 1850 to 1855
2.3:1----------1860 to 1865
2.5:1----------1870 to 1880
2.7:1----------1885 to 1895
2.8:1----------1900 to 1915

```
5:1----------------------1920 to 1930
6:1----------------------1935 to 1970
6.2:1--------------------1975 to 1990
6.3:1--------------------1995 to 1999
```

No. That is incorrect. Depending on many conditions (sunspots, weather storms, operating mode, etc) 5 watts or even less will work just fine. The key is use what is required to get the job done. Sometimes thats 1/2 a watt sometimes thats 1500 watts.

Dennis,

I assume that you are referring to 160 meters on the DX stations that you hear.

160 is a hard band to work DX on. Also the band width is very narrow as you can tell

By you SWR readings. As far as 100 watts breaking a pile up you may be surprised.

I have been a ham for almost 30 years and have worked the world on 40 meters with a

Butternut HF-6Vand 2V and have never run over 100 watts. If you have an antenna

tuner, then your antenna could be use on the other bands as well.

Just my 2 cents worth.

Joe, W4JSI

I have an inverted-L that slopes towards aPine Tree with a 12 degree slope. It goes up the tree until it reaches the top where it is 90 feet in the air and then goes horizontal for the remaining portion of the L. The total length of the wire is 138' 6" with the 38'6" portion horizontal. That yields a 90 foot vertical with a 48'6" horizontal portion.

This antenna's horizontal portion is oriented from EAST to WEST if that makes a difference. It is fed against a very modest radial field/counterpoise system. It is also fed with RG8x coax at the feed point.

The radial field consists of 5 or 6 electric fence wire pieces about 25 or 30 feet long. Held in place with metal lawn spikes that are 8-10" in length. There is a single counterpoise radial that lies on the ground somewhat underneath the top of the L. There is a second counterpoise that is only 105' in length and is doubled back with a 3' spacing of the wire.

I also tied ONE SIDE of the single story dwellings gutters and downspouts in to the radial field. THYE ONLY THING CONNECTED IN THIS RADIAL FIELD ARE THE RADIALS AND COUNTERPOISE WIRES TO WHICH THE COUNTER POISE WIRES ARE INSULATED AND THE OTHER RADIAL FIELD WIRES ARE BARE. THEY ARE CONNECTED TO THE SHIELD BRAID OF THE RG8X COAX.

The resonance regions of the antenna with respect to swr are as follows:
2.5:1----------1800

1.5:1----------1805 to 1820 15 Khz bandwidth

1.4:1----------1825 to 1855 Resonant point of antenna 30 Khz Bandwidth

1.5:1----------1860 to 1870 10 Khz bandwidth ********NOTE 1.5:1 swr from 1805 to 1870 = 65 Khz BANDWIDTH

1.6:1----------1875

1.7:1----------1880 to 1895 20 Khz bandwidth

2:1----------1900 to 1925 25 Khz bandwidth

2.4:1----------1930 to 1950 20 Khz bandwidth

2.5:1----------1955

2.6:1----------1960 to 1970 10 Khz bandwidth

5:1----------1975 to1999 24.9 Khz bandwidth

A ONE CHANGE that was made prior to the documentation above was that I checked the SWR at 1828.0 in the bypass mode of the tuner and it measured 1.6:1
B I added the North side of the dwellings gutters and downspouts to the system, re-chkd SWR at 1828.0 in the bypass mode of the tuner and it measured 1.4:1
C It dropped 2 points and I also noticed an increase in Noise level measurement----with 1.6:1 NL was S4 with 1.4 NL was S6

Since I have no modeling software nor do I know how to use it and I haven't been able to find one that is easy to use; I have no idea as to this antennas STATUS

I know it works, and I know is Hears and from what I have been told; for all practical purposes IT SHOULDN"T----------
All I am trying to do is give myself as efficient of an antenna to work 160 meters and DX and maybe other bands if possible; but my priority is 160.....I don't know if there is even a slight chance of improving this antenna thru additional counterpoise wires or not

Is there such a thing with this monster as "a point of diminishing returns?" Should I quit, or is there still room for improvement? I can't compete with a KW, but maybe I can with LOW Power or even QRP>>>

This is where skill comes in. Ask those that run QRP (<5 watts) and make the contacts in huge pileups. Like a good joke, timing is everything.

And yes, I have been known to run 1 watt at times, 25 watts is normal and 1250 watts is my max capability. I tend to use only 5 - 25 watts most of the time. I rarely use the amp outside of our traffic net.

Mode is also important. CW and PKS31 seem to be the best, with several other digital modes also quite usable.

Thanks for all the help so far on the 75ohm coax problem! It has worked well with my HT 2 meter and I can boom repeaters like they were next door! SO thanks!

Now for one last Question for awhile....
I saw in a friends magazine or a book don't remember which one it was, but it was a 10meter antenna made of 1/2 or 3/4 inch copper tube laid out in a square being fed more off center than center fed.

Have any of you seen this antenna or type pf 10 meter antenna? Do you know what the OD dimenson's could be?

I have a question on this 10m antenna. What is it mounted on?? There are several that mount a short distance above a metal ground plane. Like to top of a van, metal roof, or metal military vehicle. I believe if you look up DDRR antenna it will put you on the track to what you want.

Hi Alan,

You're welcome. I had the base of mine elevated to about 12' above ground. I was lazy in using only 3 radials (sloped) but it still worked ok.

As a sidenote, when I had the quarter wavelength vertical up, I threw a half wavelength vertical together (also 12' above ground and with three radials). When doing an A-B test, most of the time (but not always), the half wavelength vertical noticeably outperformed the quarter wavelength vertical.

Israel,

Many thanks for getting the message to Carols. We've been trying to make a connection on 14.245, but it wasn't in the cards this morning. When the Maritime Net opens we'll try again on 14.300.

I'll be participating in your special event.

From: danny garvin
Topic: 6747 Message: 6754

Hi Steven
  I have just gotten interested in Fractals my self and have been doing a lot of searches on the subject. Most of what I have found pertains to VHF and above one article I read said that not much has been done using them on HF frequencies so that area of experimenting seams to be wide open to play with. I have been thinking about playing with some HF designs but have a lot more reading to do on the subject. Maybe next spring?

Hi Y'all...is there anyone out there experimenting with fractal antennas? Anyone with a working knowledge of fractal antennas? Supposedly they are smaller yet more efficient than other antennas of similar size....What has been your experience with them?

Long ago I used to enjoy Chip W1YW's comments on another group site...

He's a very interesting chap from all I could gather and he happens to be kind of the daddy of fractal antennas.

His fractal antenna programs generate fractal patterns using inductance and capacitance algorithms to make all the patterns balance as they grow outward.

The antenna designs are basically computer generated.

I know fractal antennas are starting to be used in cell phones, WiFi routers, rfid's and the military has taken a particular interest because the antennas can be concealed easily to keep them from prying eyes...something that was a big deal way back when I was an ET in the navy.

I don't know how practical they are for hf but have seen an example or two for 10 meters.

For the upper end of uhf, I guess they have some advantages and are best rendered, for amateur use anyway, on printed circuit board material.

6756. can't tune

Yahoo group: ham-antennas (2008)
Date: 2008-11-15 03:14:05 UTC
From: Andrew Kronk
Topic: 6756 Message: 6756

I have a 40m dipole with old wire but clean connections. Makes some bends through trees on one side. Tried with both twinlead and coax (with an air balun). The coax is new. Can't seem to get it to tune. I wonder if the tuner is suspect? I use an MFJ manual Versa Tuner about 15 years old. Has anyone found that tuners degrade over time? Any ideas of what else to check would be appreciated. N8WGJ

Andrew,

I have a Versa Tuner about 20 years old. It got to acting crazy with SWRs coming out of nowhere. I subs radios, antennas, coax and finally when I changed the coax connector on the tuner the problem went away. It looks okay, but it's not. They're pretty cheap and if that solves your problem you've made a homerun.

Let me know.

Sometimes, the connector center pin works loose. I gently pry the parts towards the middle. This will make it fit tight again, until you can replace the connector.

6760. Re: question on antenna and instruments

Yahoo group: ham-antennas (2008)
Date: 2008-11-15 21:02:53 UTC
From: catboat15@aol.com
Topic: 6760 Message: 6760

I want to put up a simple dipole antenna at our present location. I can get the theoretical lengths from the ARRL handbook, but know that is not the final word in this real world. The only instrument I have is a an old "Heath kit" grid dip meter. (Well no grid to dip as there is no tubes in my solid state model)

The instruction manual I have with the meter is not very clear how to use it to find the resonant length of an antenna. Any hints would be appreciated. I will be pushing out signals through my old Kenwood S-520 and don't want to overload the final tubes by trying to push electrons where they don't want to go.

Had the same experience with a few other MFJ antenna tuners.

Those little pop rivets work for long enough to get them out the door to months and years, somtimes.

The first thing I do anymore when I get an MFJ tuner like that, is drill out the pop rivets and go back in with little screws, internal star washers and nuts...The star washers contact the cabinet after I scrape a little paint away.

Problem solved.

When it comes to the life of my rigs, I never count on those cheap-a-- pop rivets!

If you can get up close to the antenna while it is mounted, such as if it is on a tower and you climb up there. Aside from this, you can connect a couple of turns around a form that the GDO coil can fit inside of and mounted on the end of your coax. I used to have one mounted on an SO-239 so I could test my antenna back in the day. What you do is tune through and when a dip is seen, back the GDO out a little, retuning the dip. Finally you will come to a place where the dip is just barely detectable. If you can, use something to measure the frequency, such as a receiver. The GDO, when loaded like this, will pull in frequency.

BTW and FWIW, this is how it was done when I was a novice in 1960. Several of the guys from the ham club in El Paso came over and helped me get my first antenna up for 40/15 this way. No SWR meter. No one had one they were willing to bring over. And, as I remember it, I cut the antenna by the formula in the ARRL handbook, or was it Bill Orr's book.

Hope this helps.

With a Kenwood 520 you have two 6146□s and a plate and loading cap on the output, it will match up just fine. Cut the dipole according to the frequency you want to operate and use it. Unless you want a 40m dipole 10 ft off the ground it will be close enough. IMO

Think of the radiation/hearing pattern of a dipole looking like a donut , great on the side , not so hot on the ends. If you turn it upright into a vertical it will hear equally all around , 360 degrees of a circle. You might get a little more noise with a vertical .

Robert , I cannot see your antenna but most of them have a mounting bracket at the base , sometimes it will be a strap running parallel to the main mast and be about 12☐ tall, it will be insulated at the top and have the SO-239 for the coax at the bottom. If this is it, just look at the lower part , should be some holes or small bolts. This is where the radials go. If it is old make sure you clean it to get a good connection with the radials.

Alan

It depends!

Are you trying to work DX? In general, vertical has lower angle of radiation. But no directivity, which means it receives from all directions. Dipoles have some broadside directivity.

Verticals tend to suffer more from man-mande noise.

How high is the dipole? How many radials are attached to the vertical? What kind of soil? If I am at the beach near seawater, the vertical will perform extremely well for DX. At my house here in NC, the dipole on 20 meters (at 40 feet) can and often does outperform my vertical.

Dipoles are easier to erect. Do you want to use multiple bands on a single antenna?

What is your yard situation? Do you have trees to hold a dipole?

A thousand questions! Please clarify with your objectives and "yard situation" and we can give more details.

Hope this helps!

I have a 7' rod that I cut down to two eyes only for use in tighter quarters. The main problem I have isn't getting the height, it's the spool doesn't have enough capacity so on my taller trees, the weight won't make it down the other side.

I have to change the reel out for a larger one I think.

Go with round smooth sinkers and get them at least 2-3oz and it helps them drop through branches as they come down more easily.

Once the line is on the other side, you just tie off your support insulator to the fishing line and pull it back over the tree. Tape if off to cover any edges that could snag in the branches.

Once that is on the ground, you put the wire through the insulator and haul it up the tree again....don't cut off the slack once it's up and you'll be able to raise and lower the wire later on.

It mostly takes patience. If you have dense wooded area like me...good luck, it isn't easy.

Mike, just wanted to share my situation. I hired a guy who works for a tree maint. Company. I fabricated a slip strap with pulley for the person who climbed the tree using his climbing gaffs and belt. Took him a half hour to put up 4 straps on four trees. Now all I have to do is use the pulleys to put up and take down the antennas. The pulleys are in 70 foot tall carolina pines

I just have two questions:

1. How did you get the wire over the 90 foot pine?
2. Would you put a wire over the pine tree in my backyard for me please? :)

Seriously, what did you use to get that thing over the tree?

A 3-4 oz. weight/sinker was used with a small fishing pole with reel attached. It went over after 4 tries. It cleared the top and dropped to the other side. You might have better luck now with fall and winter approaching.

tip------aim high like your reaching for the stars and it will do its job.....

hope this helps Dennis in York, SC

6774. Placement of dipole

Yahoo group: ham-antennas (2008)
Date: 2008-11-17 15:39:11 UTC
From: KE7JSL@tmo.blackberry.net
Topic: 6774 Message: 6774

Question: does the placement of the dipole matter? What I mean is should it always go on top of an object or is infront ok? What about going through a large plant? I could see if it was metal that would be an issue but any other considerations? I know experiment but just asking for suggestions. Thanks.

John,
That what ham experimentation is all about! Do it for yourself and you will know. Really, you're a general class ham, what do YOU think?
Trust your instincts, not somebody across the internet. I KNOW YOU SAID just asking for suggestions, but did you know the dipole is the simplest antenna there is? You can build a dipole out of wet and dry rope! Wet for the 'hot' sides and the dry as a insulator.

Really NOT trying to be a smart a..

John,

Getting and giving information is what this group is all about.

Transmitting through anything is going to degrade your signal.

Where to place an antenna? I think the book says a quarter wave above the ground. I've never had one high enough for the lower frequencies, so I work with what I have and live with what I get.

If you build an inverted V you should keep the apex at about 90 degrees in order for the impedance 50 ohms.

You didn't ask, but most folks keep the apex on top. However, I once moved into a Texas neighborhood where it was to my benefit to keep the antenna out of sight. I put a G5RV Jr on it's side in a liveoak tree. When I was done the apex was pointed toward New England. It worked even on 750mw.

John,

If you're short on space you might consider a magnetic loop. I have a yahoo group

http://groups.yahoo.com/group/qnc/

that has some smaller antenna ideas in the file section. There's a sloper made of 300 Ohm twin lead. It's about 15 feet long and the builder claims will tune 40 and 80.

I haven't tried any of them. My present antenna is a G5RV hugging a swimming pool. I'm sure I could do better.

But don't forget the fun that can be had with an inverted v built like a fan dipole made with red, white ,and blue #12 wire strung from the top of a pine tree.Watching the 4 cars of police trying to figure out what all that wires strung up for, the looks on their face was priceless, they stood out there for at least an hour before I told them what it was for. Turned out they saw it on the way to a call about a block down which had nothing to do with me, but they decided to wait in front of my qth because they had never seen anything like it.Ike came along and took it out gotta rebuild all that's up now is an 80 meter inverted v.

Good questions , John. I do have a 5 band , Fan Dipole,80/40/20/17/10. I wish it was red, white and blue , I love that story.

Back to the point , because the wires are about 1.7☐ apart with plastic spacers , I do have a problem with rain and ice forming a resistance between the wires, OK when dry. A regular one band dipole should not have that problem.

Rich ,KDØZZ ,

from the middle of Missouri , out in the sticks with the hicks and the ticks.

It's a relic of old style majordomo email reflectors. You see them when the user doesn't remember how they signed up. The old lists, one would send 'subscribe' or 'unsubscribe' in the subject of an empty mail to join or part a list.

No way to really block them, but people think they can send an unsub message to yahoo groups all the time.... I have no idea why they don't remember to log back in and unsub, but it's pretty constant.

have you ever seen the 300ohm twinlead 2m antenna? It's virtually
invisible, I would suspect, in a tree. Google 2m twinlead jpole.

If you want to get really sneaky, you can use a piece of vertical wire,
cut for the proper band (provided you have a decent ground) or you could
make radials. About as invisible as you can get.

There are websites with antenna calculators which will give you lengths
based upon frequency.

6789. Re: [ham-antennas] Unsubscribe messages posting ?????

Unsubscribe messages aren't supposed to be sent to the group list. The bottom of every group email shows a different email address to send those unsub requests to:

But some people ignore those instructions and send them to the group anyway. (Mr. 'nlukens_1' still hasn't figured it out, I guess; or maybe he thinks it is a 'Majordomo' or some other group which recognizes the "unsubscribe" command. Yahoogroups have no such command.)

Most Yahoogroups automatically distribute everything to the whole group, without the moderator having to approve each one, so the moderator doesn't get a chance to intervene until it has already been distributed.

Andy

10 meter is about 100 inches on the upper end and one can be loaded and placed against ground wire against the house or a tree and 2 radials will get you out on it.

I've been where you're at. A dipole strung from the flagpole in the front yard, and across the roof to the back yard worked best for me. For a vertical to work with any kind of decent efficiency, you really need some radials. You didn't mention what bands you want to operate on, but I am assuming you meant low bands like 160 - 40. The higher bands an elevated ground plane is good, but the longer elements for the low bands makes this very difficult. Dipoles are the easiest. Even trapped dipoles.

I did some experiments with making dipoles from the 1/16" steel cable. You have to crimp connectors on that stuff. Elevated, the wire all but disappears. It does have some extra DC resistance, and this adds to the inefficiency slightly (maybe 10%). But, when you take into consideration that a vertical starts off at 50%, this isn't such a problem.

Thanks for reminding me how fortunate I am. I have a commercial nursery to the rear or west, a junk yard to the north, a pecan orchard to the south, and in the front, or east, is my closest neighbor, who is very pro-amateur radio. I even asked him if he noticed any problems, since my amplifier can put out 1200 watts. He is an electronics engineer and so would know if he had any.

Music wire is very strong, and can be very very thin. Making a dipole
from that would be almost totally invisible from a distance, such as
curb side overlooking your house.

The band width would be very narrow on an antenna made of such thin
wire.

No. To answer your question Steve/WM5Z
If you send the unsubscribe to the list address ham-antennas@yahoogroups.com
it will
automatically go to the group.

To unsubscribe, mail to: ham-antennas-unsubscribe@yahoogroups.com

and I believe then it won't go to the list.

You cannot simultaneously prevent and prepare for war.

Google Music wire or piano wire. Both will get you the same results.
They do even make it in stainless steel.

Hmm, looks like Yahoo edited my reply earlier today and removed the text I had after the colon. I had pasted the instructions found in every group email message "To unsubscribe from this group...".

I didn't know that Yahoo edited submitted messages like that! (Gee, if they can do that, why DON'T they block those 'unsubscribe' messages from reaching the group??)

True, but better than no antenna, right?

It would be great if no one ever had problems putting up an antenna. Some people have to do with less than ideal. I put out this suggestion because of this handicap. If it was me, I would put up a 12" diameter copper pipe, 120 feet long center fed. That should cover all of 80 meters plus a little for the MARS frequencies on either end. Should be a breeze to load up, and should handle all the power I can use, legally. Of coarse, this needs to be at 240 feet HAAT, and rotatable. While we're at it, it should be fed with 3" diameter Andrews coax to minimize losses, both on TX and RX. The coaxial balun might be a little tricky though. I think 3 feet is the minimum radius for that coax.

OK, I admit I am being outlandish.

FYI , if you are looking at stainless , thin and strong , try safety wire , it is for aircraft and race cars, used to retain fasteners. You can get it down to .020. it would be very hard to see.

6808. Re: 6m/10m FM Clandestine antenna

Yahoo group: ham-antennas (2008)
Date: 2008-11-18 00:14:54 UTC
From: Scott Laughlin
Topic: 6784 Message: 6808

Paul,

I wish you had an easier question, because I can't answer that. I just know that the finer the wire the cranky the antenna becomes and the more you have to feel with the tuner. My G5RV is a store bought antenna with probably 14 or 12 gauge wire. It's pretty forgiving, but if I move from say 14.060 to 14.300 I'll find an swr of 2:1. If it were made of arrow shaft material it would probably not need to be adjusted.

I hope that makes sense.

But you have to work with what you have. Years ago I met a fellow who lived in a trailer park. He had a randem wire antenna that was so thin everytime a storm went through he had to replace it. The court owner would have cut his ears off if he'd known about that antenna, but it was so thin only the guy who put it up knew where it was. hi.

Steve,

What you say is true. I went through Air Force electronic school, worked on the bomber naviagation systems on flightline for a decade and then worked for Delmo Victor on the antenna system for an F-111 ECM system. Don't ask me any hard questions because I'm still flying by the seat of my pants.

Leonard,

Get a sailboat.

Back twenty years ago I used to do CW with a fellow in Long Beach, CA. Antennas were bad news where he lived, but sailboat spars were horse of a different color. He had his shack in the boat. "The antenna cops haven't found this antenna yet," he said.

you could put the piano wire in a triangle say 2" to 6" on the side
that will increase the bandwidth

you would have to find a way to hide the intermediate spacers however

best

AHH yes, Yahoo DOES have email commands.and the one to leave a group is "groupname"-unsubscribe@yahoogroups.com

(you send it as a blank email; rather than putting the command in the subject line or body as Majordomo or other remailer software requires).

Yahoo allows the moderators to set the list to various settings, including moderatoring new members (until changed by the moderator) and other settings..but that is list and moderator/owner dependant. I have some lists that are totally open and some fully moderated and others in between!

Chris

WB5ITT
(Owner/moderator of 2 dozen Yahoogroups lists, including ACC, LMR, Coordinator, 222-225 and other ham radio related)

----------Original Message----------

Unsubscribe messages aren't supposed to be sent to the group list. The bottom of every group email shows a different email address to send those unsub requests to:

But some people ignore those instructions and send them to the group anyway.

(Mr. 'nlukens_1' still hasn't figured it out, I guess; or maybe he thinks it is a 'Majordomo' or some other group which recognizes the "unsubscribe"

command. Yahoogroups have no such command.)

Most Yahoogroups automatically distribute everything to the whole group, without the moderator having to approve each one, so the moderator doesn't get a chance to intervene until it has already been distributed.

Yea, I know you are joking, but the fatter the better, to a point. Do you have one of the antenna simulator programs, like EZNEC? There is an entry for the wire diameter for a reason. As the wire size gets larger, the antenna bandwidth increases. BTW, last I heard, EZNec had a free version for amateur radio use.

Years ago, the antenna builders used to make the antenna look fat by making it a wire cage. They did it because it was wider where they could tune up and operate at. Look in one of the really older antenna books.

I think it was last month on this group that someone had built a vertical for 20 meters using that concept. He was trying to get a really low SWR across the band.

I have a Alpha Delta DX-CC in my attic to handle my HF. I also have a Ventenna and a Diamond D50 on my roof painted to match the ducts for 2/70. What I'm looking for is a dual band 6M and 10M antenna that is a vertical to use the other two bands on a FT8900. I really don't want a 15' tall antenna and I only want a single antenna. I didn't put my request out very well but what I'm looking for is something less than 6' tall that does both bands without a tuner. So I probably need a trapped vertical section with loaded radials. Anyone got plans for such a critter?

6819. Re: G5RV Questions

Yahoo group: ham-antennas (2008)
Date: 2008-11-18 03:58:24 UTC
From: n0bn
Topic: 6675 Message: 6819

Thanks for the follow up question, Scott.

The center of the antenna is in the air between the handrail of the tower and a mast on the other end. I also have an extra support rope between the top of the mast and the handrail to give stability to the mast and decrease the tension on the G5RV. I have wondered whether that polypropylene rope detunes the antenna at all ... I disconnect whenever there is rain or lightning so the support rope is usually dry.

I could configure it as an inverted V with the support rope holding up the middle of the G5RV although that would significantly decrease the overall height of the antenna.

I wonder if some others in the group with much more knowledge than I might have any other suggestions or responses to my original post and the other questions I raised. At this point I'm almost at about the point where I was before I asked for advice.

Thanks.

From: Scott Laughlin
Topic: 6784 Message: 6820

Leonard,

This isn't a very good answer, but it's the best I can offer tonight. This may be the best answer I'll ever have.

The frequency difference between 6m and 10m is so great that I don't know of a way to make a dual bander. But you could fabricate two inverted Vs--one for 6 and one for t10 and hang one below the other.

You mentioned an attic, so I'm hoping you have enough rafter run to support 16' and 2" of wire. That length of wire should resonate at the center frequency of 10m. You can change that frequency for which ever side you work--cw or ssb. If you wanted the whole band the length would be that mentioned above. Hang it in your attice with the apex at the ridge line, let it droop enough so you have a 90 degree angle between the two legs to provide the 50 Ohms impendance.

The six meter is only 9 feet total--4.5 each leg. Do the same thing and suspend it on a cord a foot or so below.

Each antenna will need its own coax.

If you want to choose a certain portion of either band as a center frequency divide 468 by that chosen center frequency in mhz and when you get the length subtract an additional 5 percent from the total length.

That should work, but depending on what else is up there you may have to prune or add a half inch at a time. A half inch (1/4 from each side) will make a whale of a difference.

They should both work without a tuner giving you a 1:1 swr at the center frequency but the swr will increase as you tune away from the center. You'll have to decide what you're comfortable with and not go beyond that point.

I hope I've been clear enough on that.

6821. Re: G5RV Questions

Yahoo group: ham-antennas (2008)
Date: 2008-11-18 04:51:20 UTC
From: Scott Laughlin
Topic: 6675 Message: 6821

Daniel,

As long as you use a rope that doesn't soak up water you'll be okay. Your G5RV probably has a balan on it. I think you could stretch it out end-for-end and make a sloper of it.

My QTH is pretty cramped and I wouldn't have hung a G5RV if it hadn't come with me. It starts out on a pole then makes a 30 degree bend and follows along a wooden fence on two sides of a swimming pool. When I was finished hanging it I really thought it was a lost cause. But using a Small Wonder I was able to reach From Texas to North Carolina and Tucson using only 750mw. So it wasn't as bad as it looked. Actually, I'm striving for my 1000 mile per watt certificate. The true answer is that the G5RV gave me 850 watt miles. Sounds like a politician spinning numbers.

6822. Mixing 75 Ohm Coax with 50 Ohm Coax

Yahoo group: ham-antennas (2008)
Date: 2008-11-18 11:26:30 UTC
From: johnsobryan
Topic: 6822 Message: 6822

Hi - I am installing a new ham radio setup and want to put up a dipole on 20M for a few months and do it inexpensively until I can get a more permanent antenna (HF vertical with good coax).

But for now, I already have lying around a 50 foot run of RG58 coax (50 ohm) then a 100 foot run of cable tv 75 ohm RG58/U coax. I would need to use both together to achieve 175 feet run of total cable to the center fed homemade dipole.

Can I use both types of coax in one run? Or is that going to be a severe mismatch and result in much signal loss at 20 meters?

My rigs are Kenwood (TS-930s and 830s). Thanks!

6823. Re: [ham-antennas] 6m/10m FM Clandestine antenna

Yahoo group: ham-antennas (2008)

From: Walter A. Breining
Topic: 6784 Message: 6823

The bandwidth difference between very thin wire and wire size of let's say # 12 would hardly be noticeable. Now if we compare # 12 to a cage 3 ft. in diameter, yes the bandwidth would be greater.

Using capacity hats at the ends can increase the electrical phatness of a wire.

If I needed a stealth antenna and I had thin wire that was strong enough to stay up, I would not hesitate a minute.

Music wire is very strong, and can be very very thin. Making a dipole
from that would be almost totally invisible from a distance, such as
curb side overlooking your house.

From: Leonard K. Pennock
Topic: 6822 Message: 6824

Use the 75 ohm at the antenna end as that better matches the impedance
of the dipole. Assuming your antenna is resonant at the frequency if
interest you should see about a 1.5:1 SWR which the radios should handle
fine.

Good morning Leonard , I have been following this thread and add some of my notes now and then. I think some members have lost track of what you want.

#1 you have HF 10m SSB coverage

#2 you want 10m FM vert

#3 you want 6m FM

#4 both to be under 6□

If this is right my note about the 0,020 dia SS safety wire is not quite what you wanted. You can made a dipole for 6m and 10m FM , all in one , with one coax. It can be like your Alpha Delta DX-CC , several bands on one coax. Just run the center vertical and make the shield side into radials. Do the 10m FM first , the 6M will inter act with the 10 and have to be adjusted for best SWR. I made my own Alpha Delta type with some wire and scrap plastic and had to adjust all but the 80m wire.

You said you want it all shorted than 6□ , you can make loaded vertical or spiral wound 6 fiberglass rod but you would need two , one for 10 and one for 6. The fiberglass rod can be found at any Wal-Mart as a crappie fishing rod , Bass Pro has longer ones for up to 20M use.

Subject: Re: [ham-antennas] Re: 6m/10m FM Clandestine antenna

I have a Alpha Delta DX-CC in my attic to handle my HF. I also have a Ventenna and a Diamond D50 on my roof painted to match the ducts for 2/70. What I'm looking for is a dual band 6M and 10M antenna that is a vertical to use the other two bands on a FT8900. I really don't want a 15' tall antenna and I only want a single antenna. I didn't put my request out very well but what I'm looking for is something less than 6' tall that does both bands without a tuner. So I probably need a trapped vertical section with loaded radials. Anyone got plans for such a critter?

Thanks you have what I was looking for.

So basically you are suggesting a vertical fan dipole with 6M leg and
10M leg then? Then to get the length down use loading coils or spiral
wound?

Yes that would work , I had a spiral wound vertical back in the stone age when I was a novice on 80M CW ,it was a 10 ft stick of PVC mounted on ground level, where I was I could not put up an antenna so I had a stake in the ground and put the PVC over the stake at night, a wire capacitor hat on top, it was very narrow banded but it let me make contacts. If you need to keep the 10M under 6ft a spiral wind is a possibility. My 40m dipole was two slinkies in the attic because the attic was not big enough. I had no antenna analyzer back then just a transmitter and a SWR meter. That was 30 years ago and I am still building my antennas , have fun.

From: Steve/WM5Z
Topic: 6822 Message: 6828

I believe there would not be any problem using the two together. I would use the RG-59 coax, the 75 ohm, from the antenna down as far as it will go, then use the RG-58, the 50 ohm, to finish your run. The RG-59 has lower loss, so do any trimming on the RG-58. The SWR bump is really not that bad. It is only a 1.5:1 SWR. You will need to use real connectors for the splice, though, don't splice and tape the joints together. This will cause a nasty problem at the joint.

6829. Odd-multiple resonance

Yahoo group: ham-antennas (2008)
Date: 2008-11-19 00:16:50 UTC
From: Norm Blitch
Topic: 6829 Message: 6829

I understand the principle of odd-number harmonics giving a dipole several sweet spots. but WHAT happens when:

.consider a three wire center feed dipole with one cut for 60 meters (gives 60, 20, and 12), another cut for 40 meters (nothing gained here except 40), and the last one cut for 30 meters, yielding 10 meters as well as 6.

Do I spy a flaw here? 60 to 10 is even, as is 60 to 6; 20 is half of 40, and so on.

All three wires are connected TOGETHER in classic fashion .

Are the odd-multiples over-ridden by the evens?

From: Mike Besemer (WM4B)
Topic: 6829 Message: 6830

Norm,

If you use frequency instead of wavelength, you get slightly different results. Remember, wavelengths are approximate, while frequency is exact.

For example, 5.371 MHz * 5 = 26.855 MHz, which is pretty close to 10 meters (and is ODD). Also, 10.1 MHz * 3 = 30.3 MHz, which is also close to 10 meters (and is ODD).

7.1 MHz * 3 = 21.3 MHz, which is exactly 15 meters (and ODD).

As for 40 to 20, you're correct. 7.1 * 2 = 14.2 MHz, which is 20 meters, but the multiple is EVEN and therefore should not work on a center fed dipole.

If you feed a dipole 1/3 of its length from one end, (off-center fed) it will work on even multiples.

Now, with a fan dipole (center fed) you should see a variety of useable resonances.

Good luck es 73,

Mike

Hey, Norm, (flashback to TV show Cheers) ;-)

I don't understand your math.
5.35 X 3 = 16.3
5.35 X 5 = 37.45
7.10 X 3 = 21.3, Gaining 15 meters
10.125 X 3 = 30.375
10.125 X 5 = 50. Good for 6 meters. Where is 20 and 12 coming from?

Are you sweeping an antenna you have up? Are you modeling this on software?

dear dough
at the base of the antenna is a stepup transformer or something
just kill it out and connect your coax-connector direct to the foot-point
ad some radials and you have a nice quarterwave for 20m

dear mike
don´t know the power rating of this kind of antenna
it depends on how the transformes is built
sometimes it is very big like in the "city-star" or the "ringo-ranger" and
can easy handle legal limit
sometimes there in a very little transformer in the base that burns up with
less than 500w
but when you cut all that out and connect your feedingline direct to the
antenna and ad some radial
it will handle a gallon HI HI
73´s de dg9bfc

Depends on the 11M antenna. They range from just a few watts to over 2000W and more. Yes thats correct. Even though in the United States 11M is limited to just 5W. As to the original question you could make a base loading coil to add to each of the bands or just use a very good tuner. Personally 3 hamsticks (around $60) is much easier.

>>>5.35 X 5 = 37.45

Er..? Nope. The original maths was good.

If you happen to have a 40m dipole cut exactly for a third of 21 Mhz and also a 15m matched dipole, you will just get a slightly different interesting far field pattern than if you had either one or the other.

You can easily model this with MMANA for instance. I just did. It took 20 seconds.

Cheers,

Callum McCormick

Hey, Norm, (flashback to TV show Cheers) ;-)

I don't understand your math.
5.35 X 3 = 16.3
5.35 X 5 = 37.45
7.10 X 3 = 21.3, Gaining 15 meters
10.125 X 3 = 30.375
10.125 X 5 = 50. Good for 6 meters. Where is 20 and 12 coming from?

Are you sweeping an antenna you have up? Are you modeling this on software?

Is it one of those 20 some foot long antenna? I think they were touted as being 5/8 wavelength. Those have a coil in the base that you will need to remove. Then you will need to make a loading coil and feed it. It can be done. It should work pretty well, especially if you can mount it on a decent radial system. You could even use a variable inductor, motorize it, and make it work anywhere from 3.5-10.15Mhz remotely.

If it is a 1/4 wave, it would also work, but it would need a bigger inductor, and would work about as efficiently as a mobile antenna.

The power limitation was for the coil in the base. It was made on a PC board. Those would handle at least 100 watts, but he would be removing that.

18 feet and 3 four foot radials??? looks like a 5/8 gpa
but it is the same ... cut out the wire transformer or coil
feed it direct and ad some resonant radials
and cut the antenna for quarterwave on 20m
maybe is will work with letting the last extension away
don´t know the exact lenght of your antenna BUT it can be rebuilt for 20
like i explained before

From: de K6KAW
Topic: 6847 Message: 6847

Greeting to all on the groups....

Just got my HF station on the air. ***** WOOOO HOOO ****

OK nufff said. Been scanning the bands par to what that my antenna covers.
Worked HI., CO.,VE6, Have not had much time to play. OK here is the story.

I have a constant noise floor of S7 to S9 most of the time. Is this normal??

OHHHH!! Here is the station info.

Apartment in CM87xx,
Second floor,
Yeasu FT-857D,
Antenna is an Alpha Delta DX-EE covering 10, 15, 20, and 40. Antenna is on
the roof, 25' in an inverted V format. Legs of the DiPole run W - E. Antenna
is mounted to the support upright for the rail for the walkway. Match
is OK on all bands but 40. I understand with this antenna 40 can be a
challange.

Grounding is an issue.... Main panel box is across the room over 20'
away. Grounded
3 prong plug is right here & used.

What does everybody think ????

I would love to get on and work. I think my ears are plugged :-)

No, but adding some resonant ones for whatever band/s you want to use
isn't hard.

Subject: [ham-antennas] BIG NOISE FLOOR !!!

Greeting to all on the groups....

Just got my HF station on the air. ***** WOOOO HOOO ****

OK nufff said. Been scanning the bands par to what that my antenna covers.

Worked HI., CO.,VE6, Have not had much time to play. OK here is the story.

I have a constant noise floor of S7 to S9 most of the time. Is this normal??

OHHHH!! Here is the station info.

Apartment in CM87xx,

Second floor,

Yeasu FT-857D,

Antenna is an Alpha Delta DX-EE covering 10, 15, 20, and 40. Antenna is on

the roof, 25' in an inverted V format. Legs of the DiPole run W - E. Antenna

is mounted to the support upright for the rail for the walkway. Match

is OK on all bands but 40. I understand with this antenna 40 can be a

challange.

Grounding is an issue.... Main panel box is across the room over 20'

away. Grounded

3 prong plug is right here & used.

What does everybody think ????

I would love to get on and work. I think my ears are plugged :-)

Subject: [ham-antennas] 11m 1/2 wave antenna mod

Hello Group,

I have an old Radio Shack 11m 1/2 wave base antenna from the '70's. Is

there any type of mod that can be performed on it so that it can work

80m, 40m, or 20m?

Cheers!

Doug...

6853. Re: Placement of dipole

Yahoo group: ham-antennas (2008)
Date: 2008-11-20 00:55:13 UTC
From: Richard Fredrick
Topic: 6774 Message: 6853

Hi John,

I can't remember the source, but someone did a comparison of the effect that various types of trees had on HF emissions. As I recall a deciduous tree was less likely to affect the signal than a conifer. General rule of thumb is to stay clear of metal objects such as rain gutters. And if you're putting up an inverted V, make sure that the ends are high enough so that people won't come to harm if they get too close.

I'm just in the planning stages for my HF station and I'm reading everything I can get my hands on about grounding and other considerations. Now that the leaves have fallen from the trees I'm trying to figure out the geometry for a dipole that will be strung between a tree in the front yard and one or two trees in the backyard, while keeping clear of the electrical supply coming into the house.

And I've got a really nice addition to my plans: metal siding! I'll be running coax under ground to the window line that actually goes up to the antenna.

As I was reading this thread I remembered when I used to fly I had to check the safety wires as part of our preflight inspection on our taildrager which were made of stainless steel wire and then remembered also the brass safety wire as well. Well here is a great link for spools (only 25 foot though) or one pound boxes.

http://www.aircraftspruce.com/catalog/appages/safetywire.php

They also have the nice tools for making nice clean twisted connections fairly cheaply. They have all kinds of cool things for aircraft that can be used by those of us who are hams.

Thanks for the link Paul , I also worked around aircraft and brought up the safety last night , but I got to thinking and the safety wire is strong and flexible, , ok for a dipole that would be too thin to see, but for a vertical you might want to look at music wire. It is not as flexible and has a good spring rate. The original request was to have it under 6 ft , he could use a piece of music wire from a hobby shop and solder it to the center of a lower section of rod to get the required height and not be seen. Ref the picture of the splice of SS rod in the picture section where I put a 1/16 rod in a 1/8 SS rod. 1/16 or less is hard to see at a distance. Just drill the lower section and use a good flux and clean it up when done.

Dave,
Use the 75 Ohm to make the antenna as the impedance doesn't matter, just the velocity factor. Then use 50 Ohm for the feeder, as all the formulas/calculators I've seen calculate the antenna dimensions for a 50 Ohm feed-point.
I have double bazookas on 60M; 40M; 6M; & 4M. I like them. They work.

6861. SuperLoop Experience

Yahoo group: ham-antennas (2008)
Date: 2008-11-20 15:53:06 UTC
From: William Trippett
Topic: 6861 Message: 6861

Having become very intrigued by th so-called "Super Loop" I built two of them for 40/80 meters. There did not seem to be enough difference between them to justify keeping both of them so I rebuilt one of them into a 30 meter antenna. Using EXNEC the dimensions are as follows: Horizontal section 64.8 feet. Equilateral sections, 43.85 feet. The horizontal section is split in the middle with a 1/4 wave stub of 450 0hm ladder line attached across the insulator. The unit is fed at the vertex with a 4:1 balun and shows 200 +j0 with0ut the balun.

The antenna is at 85 feet and works very well on 30 and well enough on 60 meters. Interestingly it tunes 20 meters well too although I don't use it for that band.

Also of interest is the fact that the SWR plot shows significant dips at about 3.4 and 23.5 MHz.

Using my antenna analyzer the antenna actually dips at about 9.9 MHz instead of the design frequency of 10.125. That can probably be attributed to differing conditions than the assumptions used in EZNEC.

Anybody else used one of these?

Oh gosh Norm,

EZnec is pretty easy to use. Since it is a graphical interface for NEC. It is to bad for me, I use Linux, and it doesn't run on Linux. My last experience with EZnec was back about 4 - 5 years ago before I changed from XPpro to Linux. Maybe someday someone will write a version for us Linux kind of guys. Until then.

Anyway, either way you go, up or down, if you are designing an antenna, and want to know what it is capable of, that software can help. True, it is only a model, and can't possibly predict every scenario. But it sure can save a ton of wire :-)

Thank you very much. Let me offer you that if you need a beta tester on Linux, I am willing.

Have you thought about making a Linux native version? Those of us that use this operating system would really like that.

Mike, this makes me thing of two things right off the bat --

First, I've seen mounts to fit in a stake pocket. Seems that might be a bit easier to handle.

Second, use a quick-disconnect. I think the Hustler one would be pretty easy to manipulate with your sore hands, as it gives a pretty large surface to grip.

As for not being so high -- well, you could certainly get a 2-foot Hustler mast and put a 20-meter resonator on it. This gives you a 20-meter antenna that is only about 4 feet long. They work OK, but as you know, the longer, the better in a mobile application.

Fix the mount and use quick disconnects. I recommend the Hustler QD which is very well made. One half twist and its off!
I use it on my Tarheel model 100 to remove the whip.. with it removed I can do car washes, and garages with no trouble!

Consider the motorized antenna mounts that raises (swivels) up/down...

Diamond K9000 series (www.eham.net/reviews/detail/6171) with photos at (www.rfparts.com/diamond/k9000photos.html).
Maldol MK-30H motorized mount at (www.universal-radio.com/catalog/hamantm/4219.html). These may or may not be suitable for your install. I would think that a stake hole mount could be readily made if needed or just mount to a bed rail. There may be others that could be brought up in a web search.

Or perhaps a short screwdriver antenna with a fold-over release... (www.hayseed.net/~jpk5lad/Tahoe mobile installation/HF Antenna Installation/Little Tarheel Installation/Screwdriver Ant for 2007 Tahoe.htm) and (www.tarheelantennas.com/little_tarheel_ii). These little antennas could clear the truck roof when stake hole mounted if the whip is laid down or quick disconnect is used.

Just a few ideas... I hope you find what you need.

Here's my situation fpr comments, and may help: I have a 20 m dipole at 35' and a cushcraft 5 band vertical with 16 radials - all over very rocky terrain. In all but a very few instances the dipole gives better reception (generally 2-3 S units). Ditto for my 80 m dipole at 35-40', which usually oiutperforms the vertical.

The vertical was fun to play with and set up, but for the most p;art I just use my dipoles.

But now a neat experiment would be. it to re mount yout vrttical about 5
to 10 feet above the ground, and use the same amount of radials, but
also elevated at the same height. I bet you would be surprised at the
difference.

6875. Stealth 40 or 20M Beam

Yahoo group: ham-antennas (2008)
Date: 2008-11-21 03:38:59 UTC
From: Steven Read
Topic: 6875 Message: 6875

I have a tower for my TV antenna and am wondering whether there would be any way to replace the TV antenna with a 40 or 20M beam without it being too obvious. Has anybody tried anything like this? The tower is about thirty feet tall and I am looking for something where the switch from a TV to ham antenna would not be too visible from the ground. The house with the tower sits back about forty feet from the street.

If you own your home, an idea would be to get your wife to raise some sort of flowering plant - something that needs a trellis. You should be able to bury some chicken fencing in the flower garden.

A little more detail about your situation might give folks on the list some ideas.

6877. Be Careful How You List Names In Your Cell Phone

Yahoo group: ham-antennas (2008)
Date: 2008-11-21 05:59:27 UTC
From: Its from KE4VYN
Topic: 6877 Message: 6877

I have seen this before, and while not radio related it never hurts to have a reminder. The holidays are coming up.

Something to think about & maybe make a change?

Be careful how you list names on your cell phone! This lady has changed her habit of how she lists her names on Her mobile phone after her handbag was stolen. Her handbag which contained her cell phone, credit card, wallet, etc.. was stolen. 20 minutes later when she called her Husband from a pay phone telling him what had happened, hubby says 'I received your text asking about our Pin number and I've replied a little while ago.' When they rushed down to the bank, the bank staff told them all the money was already withdrawn.

The thief had actually used the stolen cell phone to text 'hubby' in the contact list and got hold of the PIN number. Within 20 minutes he had withdrawn all the money from the bank account.

Moral of the lesson: Do not disclose the relationship between you and the people in your contact list.
Avoid using names like Home, Honey, Hubby, Sweetheart, Dad, Mom, etc.

And very importantly, when sensitive info is being asked thru texts, CONFIRM by calling back. Also, when you're being texted by friends or family to meet them somewhere, be sure to call back to confirm that the message came from them. If you don't reach them, be very careful about going places to meet 'family and friends' who text you.

They could be setting you up to be burglarized, or worse. PLEASE PASS THIS ON.

6878. radial/counterpoise

Yahoo group: ham-antennas (2008)
Date: 2008-11-21 08:32:48 UTC
From: Rick
Topic: 6878 Message: 6878

Question is
When is a radial a counterpoise? In other words if you have a wire/radial elevated above ground around 12 inches or more is this a radial, a counterpoise or other leg of a dipole. The other wire would be connected to a 40 ft vertical wire. If this would be considered the other leg of a dipole I would assume that this leg would not have to be grounded, am I correct in this?. The center/tie point would be connected to a 1:1 balun. I am not sure so I figured I would come to the pool.

Thanks
Rick/WA6ES

6879. Re: [ham-antennas] hf vertical v dipole

From: Walter A. Breining
Topic: 6762 Message: 6879

Alan:

A vertical will have a lower radiation angle than a dipole. It will sometimes hear more noise, but for DX the advantage of the low angle will often out weigh this problem.

Simply, I have found that a properly erected dipole is usually superior to a vertical for distances out to about 800 to 1000 miles. Farther out the vertical is usually superior if it is properly designed.

Since 20 meters is a DX band, I have found that a vertical is superior to a dipole because my interest on that band is stations over 800 miles.

At one time I had a 20-meter ground plane on my barn roof and it was far better than the dipole. I later put up a good tri band beam and I was surprised at how well the ground plane kept up with the beam. Now understand that the ability to reject unwanted signals by the directional characteristics of the beam was a big advantage, and the beam exhibited some improvement over the ground plane on transmit.

Also on 80 meters I had a ground mounted ? wave vertical and a dipole. Again I found that the dipole was usually superior to the vertical out to about 800 miles. But out farther than 1000 miles the vertical was usually superior to the dipole. The vertical was very much the better antenna for receive and transmit it Northern Europe.

Since 20 meters, at least to me, is a DX band if I could not have a beam I would choose a vertical.

You'll get a lot of opinions on this. When I was in college, studying for my EE, we never used the word "counterpoise". It's not in any college or scientific textbook that I ever recall. Somehow, this term made its way into ham radio through some publication to describe the other end of the antenna.

The idea is to allow the return currents to increase efficiency and to affect capacitance, etc. This is why the more radials you have, the better. A minimum would be 4 for a vertical above ground and roughly 30-40 for a ground mounted vertical. One "counterpoise" and one radiating element is a dipole, two poles...

A perfect example of throw up a wire and see what happens is my
location. I have a dipole up that technically should be next to
impossible to work Hawaii, but it does and very well at that.
So you just never know what might influence it.

A radial IS a counterpoise. A counterpoise is the so-called missing half of a vertical whether it is one wire or many or a copper wire mesh screen laid out on the ground. If I remember correctly the term "radial" comes from having a set of wires arranged around the base of a vertical antenna in such a manner that they "radiate" out from the center like the spokes on a bicycle tire.

I think that the counterpoise on a vertical, as in my HyGain AV-640, is not quite the same as the radial. Radials are best when cut for 1/4 wavelength, whereas, my counterpoise is not 1/4 wavelength. The counterpoise is always elevated at least 7 feet, has a capacitance to ground and to the vertical element. One length of counterpoise fits all bands, as in the AV-640 multiband vertical.
In the case of the AV-640, the vertical is 3/8 electrical wavelength, and the counterpoise elements are far less than what you would expect the other side of a vertical should be.

A good reference is at http://www.antennex.com/shack/Dec06/cps.html
by L.B. Cebik. (SK)

Excellent advice.

Allow me to amplify: don't list ANYTHING.

I'm also agitated that ham licensing info gets publicly listed. Do I really want anybody knowing what I do or equipment I might have at that particular address?

It's almost as silly as nurses having RN plates. Invitation for theft (or worse).

The point I was trying to make is that "counterpoise" is more of a ham radio term, not a scientific term. The common use by hams suggests that it means the other end of the dipole. Or some refer to it as the "network of wires to act as a ground" which sounds like a radial system.

But go to a commercial antenna reference manual and you'll not likely see the term used professionally. Later tomorrow, I'll do a search in some of my reference materials to see if I missed something.

A radial IS a counterpoise. A counterpoise is the so-called missing
half of a vertical whether it is one wire or many or a copper wire mesh
screen laid out on the ground. If I remember correctly the
term "radial" comes from having a set of wires arranged around the base
of a vertical antenna in such a manner that they "radiate" out from the
center like the spokes on a bicycle tire.

Leanord, sorry for catching this thread so late. Sounds like you are a candidate for a screwdriver antenna. The smaller versions (SDA and MFJ)offer 6 to 40(or 80) meter coverage. Should stand no more than 5-6 feet tall. Might be a little more elaborate than you intended but option none the less.

God bless

From: Rick
Topic: 6878 Message: 6895

Thanks for the answers for the first part, I think. Sooo the way I see it if I have insulated copper wire streched on the cinderblock fence around 12-18" above the ground this would be considered a counterpoise/radial only if I have more than one stretched out. If I have one stretched wire stretched out it would technically count act as a "dipole type" antenna. In eather case I will be using a 1:1 balun.

Counterpoise?
On the Use and Abuse of a Word
L. B. Cebik, W4RNL

The term counterpoise has a long history in antenna engineering and amateur practice. Today, it may be among the most misused terms in amateur circles. Indeed, if we examine both the history of the term, its meaning, and its misuses, we might reach an interesting conclusion: there is no such thing as a counterpoise in antenna analysis, even though the term has a long and somewhat respectable use in antenna engineering.

Although my bookshelf has many gaps and covers antenna history in fits and spurts, we can detect some trends in the use of the terms, along with the seeds of misuse. Therefore, let's begin with a small informal history of the term counterpoise.

6898. Re: [ham-antennas] Re: radial/counterpoise

Yahoo group: ham-antennas (2008)
Date: 2008-11-22 14:41:01 UTC
From: vaclav sal
Topic: 6878 Message: 6898

I think the term "counterpoise" originated and is primarily used when the ordinary in-line, co-linear dipole half is no longer physically in line. Rearranging the dipole half in other than in-line affect dipole properties, one of them being the radiating pattern. Orient the dipole half's in 90 degree angle (either horizontally or vertically) and see what the model shows.
It may not be a scientific term, but it tells me that I no longer have a plain ordinary dipole configuration. Just help-full term, I guess.
73 Vaclav AA7EJ

PS And since this sounds more like splitting hair - here is another one for the group.
Does an antenna have "radiating" or "radiation" pattern?

Steve,
Point taken re Modeling...
In Truth, however, as of last night, just before Local sundown, the dipole(s) IS working on 20, 30 (my first Q on 30!)... 40 seemed dead at the time, maybe a tad early to use? No SWR analysis yet, so no pruning. All things considered, VERY happy with the antenna (based on the AlphaDelta center connector) towering 12' AGL at the hoist... Now on to a 40' push pole!!

6902. Introduction

Yahoo group: ham-antennas (2008)
Date: 2008-11-22 22:06:41 UTC
From: J Sullivan
Topic: 6902 Message: 6902

I have been a ham twice, the first time back in the days when it was a one-year term, 75-watts & xtal control, most recently as a Technician. I lost interest in the transmitting aspect of the hobby after I had the chance to move to a very high location in Central New Jersey where I got to indulge my monitoring interests, first with military aircrtaft, then with low-band skip & most recently with operating 2 railroad scanner mp3 streams on the Internet.

I wasted less than a year before putting up an ICOM discone on my chimney fed with 1/2" hardline to my ICOM R-7000. I've since experimented with a range of different antenna types:

Create LPDAs (both horizontal & vertical polarization on rotators)
6-Meter rhombic (concept only. I have a big back yard!)
AS-3886/TRC-191 SINCGARS discone (30-88 MHz, in attic)
OE-254/GRC bicone (on rear deck)
2 Traintennas (160-162 MHz gain verticals) fed with Belden 9913
Helical UHF antenna for MILSATCOM (homebrew project that was published in Monitoring Times)
AS-3900A/VRC SINCGARS HUMVEE antenna (another fine RA Miller Industries product)

Pending the start of the next sunspot cycle, I spend most of my time listening to the area railroad chatter from the Motorola GM-300 transceiver that is the basis for one of my streams while my BC-895XLT patiently scans for military skip (151.4 Hz CTCSS decode).

I have become interested in novel wideband antenna designs & spend most of my time searching US Patents on novel antenna designs.

The bulk of my skip loggings have been ham signals - 10-meter FM from Japan, Africa, Germany, the Carribean & India, 6-FM.

Jack

6903. RE: [ham-antennas] Introduction

Yahoo group: ham-antennas (2008)

Great story Jack. Like you I am looking forward to a sunspot maximum since I have never been in the RF hobby during this time. This is my third venture into radio and I'm gonna make sure I have at least one sunspot maximum!

Cheers from Birmingham,

Callum McCormick

http://www.m0mcx.co.uk/

Some people ask me what M0MCX means. It stands for Mike Zero Mike Charlie Xray; a callsign assigned to me by the Office of Communication (Ofcom). I have a callsign because I'm an amateur radio operator (ham radio). It doesn't stand for my MOM and the 0 in the callsign isn't a frigging O for Orange (we say Oscar), it's a ZERO. My MOM has nothing to do with my email address, OK? Thanks.

Topic: 6902 Message: 6904

Hi Callum & thanks!

The last cycle was pretty good but I'm told it didn't hold a candle to the one before.

As one example of what you can expect, 2 hours after local sunset here on the East Coast puts the sun over the mid-Pacific & it's very early AM in Japan. I could typically log a dozen JA stations on 29.60 MHz within 30 minutes, with no US domestic stations in evidence. And it was a real hoot to listen to 37 MHz taxis & taxi dispatchers from Rio de Janeiro on almost a daily basis. And Argentinian hams were also common on 10 meters. It is definitely an experience to look forward to & plan for.

If you notice most of my low-band antennas are broadband, a real necessity when you are hunting for signals anywhere between 25 & 100 MHz. Polarization is not critical but having a resonant antenna system or two is a must.

BC station harmonics were also common above 30 MHz. BBC, VOA, Deutsche Welle, etc. It pays to have an all mode reciver when you catch AM signals as well as a directory of HF BC stations. And another plus is having a receiver than can decode & report CTCSS tones, which are pretty standard in this hemisphere.

Good luck & let us know when you start hearing skip.

Jack

Make it look like something else!
Nobody will say anything about a flagpole or two. You can either get one in plastics/fiberglass and fit a radiating element inside or get a metal tupe make a insulating base tune it to lenght and fit endcap annd a flag.
You probably have to make one for each band but that will show that your very patriotic :-)

Rod,

Depends a lot on your bike, your radio and what you want to do with it.

I have my Yaesu FTM 10R on my Harley Ultra. I separated the head end from the body, mounted the body in the Tour Pak, head end is on the handle bars, external speaker is on the handle bars, use a no ground plane 1/2 wave antenna and it works fine.

If you have "naked" style bike, mounting the radio and antenna my be a problem, also you may need to check the charging system. Most ham radios are not to bad on RX but will pull 20+ amps on TX. Can your bike handle that? A lot of the smaller bikes or "crotch rockets" cannot.

It is fun to reply to some one that you are "Motorcycle Mobil". They usually don't want to believe it.

Google hf loop antennas. I hear they work real well. MFJ has several "apartment" style antennas. Hope that helps.

Thank you Paul. I ride a 2007 Yamaha V Star 1100
with leather saddlebags. I just mounted a NMO mount
on the upper left corner of my license plate and it
seams to be pretty solid. I can use either a Icom 2000
or a Kenwood V7a and separate the body and head
like you did. I am hoping to get by with 5 watts. The
repeater is about in the middle of the Marathon, but
the Marathon is in a canyon. I will look at buying a 1/2
wave antenna. Motor noise, have any?

Rod

Hi Rod,

I've run 2m APRS on a motorcycle for several years. A J-pole has worked best for me. I've built several from 300 Ohm twin lead and slip it inside a section of 1" pvc. You can go to 10 Watts on the twin lead, maybe more if you do short transmissions. Sometimes the SWRs are erratic on that antenna, so choose enough coax so you can make a decoupling coil, four loops six inches across and close to feed point will usually take care of that.

If you need plans for that J-pole let me know and I'll rush them to you.

If you need ideas on a mic, ear buds, PTT switches etc. and such you might consider joining the Bicycle Mobile Hams of America on Yahoo. They have a fifteen year history of what's worked for them. What works on a bicycle will certainly work on a mtorcycle. The newsletter editor has a couple of Goldwings that are radio active. You'll find his call on the home page. He'll be delighted you asked.

I hope this has helped.

Rod,

Remember, for good communications Antenna! Antenna! Antenna!

The V Star should handle the radio electrics easily.

No alternator noise at all, however, I did install a Kenwood PG-3B Noise Filter on the power line to the radio and wired the radio directly to the battery.

You have to look at something like a marine antenna. These are usually end fed 1/2 wave antenna. If it will work on a fiberglass boat or car, that is what you need.

Subject: RE: [ham-antennas] Re: Introduction

Jack, at the height of the cycle, 20m is clearly open 24 hours per day. I?m

trying to judge where it ends; can one work DX on 10m 24 hours per day ? or

will 10m shut after sun down?

Cheers,

Callum McCormick

Subject: [ham-antennas] Re: Introduction

Hi Callum & thanks!

The last cycle was pretty good but I'm told it didn't hold a candle

to the one before.

As one example of what you can expect, 2 hours after local sunset

here on the East Coast puts the sun over the mid-Pacific & it's very

early AM in Japan. I could typically log a dozen JA stations on

29.60 MHz within 30 minutes, with no US domestic stations in

evidence. And it was a real hoot to listen to 37 MHz taxis & taxi

dispatchers from Rio de Janeiro on almost a daily basis. And

Argentinian hams were also common on 10 meters. It is definitely an experience to look forward to & plan for.

If you notice most of my low-band antennas are broadband, a real necessity when you are hunting for signals anywhere between 25 & 100 MHz. Polarization is not critical but having a resonant antenna system or two is a must.

BC station harmonics were also common above 30 MHz. BBC, VOA, Deutsche Welle, etc. It pays to have an all mode reciver when you catch AM signals as well as a directory of HF BC stations. And another plus is having a receiver than can decode & report CTCSS tones, which are pretty standard in this hemisphere.

Good luck & let us know when you start hearing skip.

6923. Recommendations for Long Coax Run

Yahoo group: ham-antennas (2008)
Date: 2008-11-25 13:53:49 UTC
From: johnsobryan
Topic: 6923 Message: 6923

Hi - I have a rather long run between my operating station and my vertical antenna that I'm proposing to install. The total length will be 360 feet of coax to get out to the field where I will install a vertical antenna (most likely the ZeroFive vertical).

I operate mostly on 20M, 17M, 40M running a Kenwood 930s.

Question - I'm looking for recommendations on coax for long runs and realizing it's a long run, something that won't break the bank either. I will propose to bury the cable for about 100 feet of the run, and it must go across my roof which is metal.

I have a bunch of cable TV coax (RG6/U) lying around that I could use but I'm not sure if the losses would be too great using the RG6.

Has anyone run several hundred feet of coax and if so, what did you end up using as the coax of choice?

Thanks very much.

6924. Re: [ham-antennas] Recommendations for Long Coax Run

RG6 has low loss but I would try to use ladder line if possable the loss of RG6 for that run would be 2.5 db on 40m, 3.5 db on 20m, 4.0db on 17m. At 3db you are loosing 1/2 your power before you get to the antenna. With ladder line the losses would be 0.6db on 40, 0.882 on 20m, 1.007 on 17m as you can see a major difference. hope this helps.

Topic: 6923 Message: 6926

Well, since he is wanting to go across his metal roof, and since he
wants to bury the feedline for at least 100 feet, this is not feasible
for him.

Although my runs both are only at 120' I use LMR400. My vertical is an
AV620 and it is at 125' of coax. The dipole has 120' of coax, that goes
to the tower, and some made into an RF choke at ground level.

If you could afford bigger, I'd sure go with it.

6927. RE: [ham-antennas] Recommendations for Long Coax Run

Yahoo group: ham-antennas (2008)
Date: 2008-11-25 15:22:36 UTC
From: Richard Schmuke
Topic: 6923 Message: 6927

That is a long run for coax and way too long for RG-6 size on 17 & 20, IMO. If it has to be that far way I would look at ladder line 450 or 600 Ohm not 300. The ZeroFive is a good product but you can make your own, cheaper and have fun doing it. You can mount it at ground or elevated with a small tilt unit. See my home made tilt unit for my vertical posted in the photo section. I have one for my home made beam and J-pole and one for my vertical. The picture was taken before the vertical was installed , I was just showing the home made tile over.

Rich ,KDØZZ ,

I don't think you can bury ladder line and have it work very well. Also, you will have to be carefull how you run it across the metal roof. COAX is what he should be using. RG6 should work but the impedance is 75 ohms instead of 50, but that might not be a problem.

6929. Re: Antenna ideas

Yahoo group: ham-antennas (2008)
Date: 2008-11-25 18:31:49 UTC
From: ash_lee52
Topic: 6908 Message: 6929

I would say go with a wire... it will probably never even be noticed. I have 5 wires up in my "no antenna" community, and do just fine. The easiest may be a Par EndFedz (see eham.com reviews)because you can more easily hide the feed line feeding an antenna from an end. These work well hung as verticals from trees, or as slopers. I have a little hoisting line made from fishing line (dark fly line) to use antennas hoisted up the side of my house.

A classic inverted V is also usually pretty easy to hide when you put the middle in a tree and take the feed line up alongside the trunk. Use fishing line to hold the ends out.

Two other solutions might work well for you. Check out the TW Antennas Backpacker model. This is a compact vertical dipole for 20 meters through 10, that you can set up or take down in 2 minutes... and it really works well. Most people would never identify it as an antenna. I even did a contest once with mine in the living room. These are frequently sold new, at a discount, on E-Bay.

Finally, the classic suggestion is to put a really efficient antenna on your car and run coax to that from your apartment when you want to operate there. Adding a temporary elevated radial will probably boost performance considerably, since grounding is a fairly big issue for mobile antennas.

Some people might also suggest the BuddiStick because if its extreme portability. These can be very efficient with a single elevated radial. I find them a bit fussy to tune, but if you are going to be using it in the same spot again and again you only need to tune it once and leave taps on the coail for each of the bands you use.

Basically, if prisoners of war managed to hide antennas and radios in prison camps in WWII, you should easily be able to hide something. In my opinion a Par EndFedz set as a vertical is the most efficient vertical there is, so you needn't sacrafice effectiveness for stealth.

Matthew , are you renting a house?? or apartment?? Do you have a porch or balcony??

I have been in that position years ago. Let us know what you have so we know what to say.

Rich , KDØZZ

6931. Re: Recommendations for Long Coax Run

Yahoo group: ham-antennas (2008)
Date: 2008-11-26 00:36:52 UTC
From: johnsobryan
Topic: 6923 Message: 6931

I appreciate all the advice and if it weren't for the metal roof and having to bury at least a portion of the cable, I'd go with ladder line because of low loss. Perhaps I could run coax across the roof and buried portion (about 100 feet) then the rest of the 260 feet could be ladder line? I'm not sure how that would work, whether I could just hook up coax to ladder line, etc but I'd be interested if anyone has used both in the same run to the antenna.

Thanks.

6932. "Low noise" wire antenna...?

Yahoo group: ham-antennas (2008)
Date: 2008-11-26 01:11:49 UTC
From: wa6spa
Topic: 6932 Message: 6932

Hi all ☐

I've got severe power line noise issues here, and while local hams from my club, and our electric company, are trying to track down the culprit (they say it's being carried over the lines from `somewhere', being detected by my antenna, and entering the shack that way.

As I'm using a vertical antenna, which are normally more susceptible to man made noises than a wire antenna, I think it's best to switch to a "low noise" wire antenna until the problem is corrected.

I found something called a T2FD which is described as a low noise wire antenna, and it looks promising, but was wondering if anyone who has had similar power line noise problems could recommend a their wire antenna choice?

Thanks.

I don't think you can bury ladder line and have it work very well. Also,

you will have to be carefull how you run it across the metal roof. COAX is

what he should be using. RG6 should work but the impedance is 75 ohms

instead of 50, but that might not be a problem.

Some people have used their metal rain gutters as an antenna. Some use a thin wire antenna that is hardly visible. Lots of things can be done so look up "stealth antennas" on the net in ham radio sites.

Your greatest concern is what will the SWR be on the feed line?

As I understand it, the Zero 5 antenna is a non-resonant antenna and its is design is to be used with a tuner at or near the base. If the tuner is mounted at the base all is well. If you are planning to have the tuner in the shack, you will have big problems with losses no matter what way you go.

So this leaves me with a lot of questions.

Are you really an avid Dxer? The vertical will usually be better than a dipole for distances of over 1000 miles but a dipole will usually outperform a vertical at distances of 800 miles or less.

Why are you wishing to place the antenna 360 ft from the shack. Is it for height advantage? How much height advantage? On HF height above ground level is important in achieving a low angle for DX but height above sea level has little advantage with sky wave unless you are very closely boxed in.

I had a 50-ft. push up pole ground mounted and fed against a ground rod and radial system. It was fed with 75 ft. of Belden RG8U. While it did very well for DX with the manual tuner setting at the base of the antenna providing a near 1 to 1 match to the feed line, it performed very poorly if I placed the tuner at the shack end of the feed line due to the multiplied line losses caused by standing waves on the feed line.

So again, I ask why are you going 360 ft. from the shack ? If this is necessary, perhaps something such as a Hy Tower that has a resonance on each band and Heliax as a feed line would be a better choice.

Resonance in and of itself has very little to do with antenna gain or efficiency. The losses on a feed line caused by a high standing wave on the line are another matter. We all wish that we could hook a coax to a random length radiator and match it from the shack. Unfortunately life is not that simple.

I was devastated when I learned that everything in Physics was neither linear nor conjugate.

Tell us more.

Subject: [ham-antennas] Recommendations for Long Coax Run

Hi - I have a rather long run between my operating station and my vertical antenna that I'm proposing to install. The total length

will be 360 feet of coax to get out to the field where I will install a vertical antenna (most likely the ZeroFive vertical).

I operate mostly on 20M, 17M, 40M running a Kenwood 930s.

Question - I'm looking for recommendations on coax for long runs and realizing it's a long run, something that won't break the bank either. I will propose to bury the cable for about 100 feet of the run, and it must go across my roof which is metal.

I have a bunch of cable TV coax (RG6/U) lying around that I could use but I'm not sure if the losses would be too great using the RG6.

Has anyone run several hundred feet of coax and if so, what did you end up using as the coax of choice?

Thanks very much.

Two runs of COAX or hard line won't work because of the shield on the coax. Ladder line, open wire or flat lead in work by the lines of electromagnetic force (EMF) around the two conductors. The conductors have to be spaced uniformly to get a constant impedance over the length of the line. That is the purpose of the "ladder rungs". the EMF cannot be disturbed by being close to a conducting object, like the roof, or the ground, so stand offs have to be used to support it. trying to use two coax cables to emulate open wire feed line, would not work because of the shield on each center conductor. Even if you tried to use the shield, you could not keep the distances between the conductors constant , so the impedance would not be constance and you would have a lot of reflected power.

Here is a table comparing RG6 loss values

http://www.tessco.com/products/displayProducts.do?groupId=408&subgroupId=22

It looks like it is about 2 db per 100 feet at HF, so 360 feet would be
a loss of about 8 db.

RG8 has a lower losses, on the order of 1.2 dB/ 100 feet.

http://www.tessco.com/products/displayProducts.do?groupId=403&subgroupId=20

so 360 feet would be a loss of about 5dB. That 3 dB difference between
the two means rg 8 will give you twice as much power at the antenna than
rg6 will give you. (100 % increase in power or 50% decrease is a 3 dB
change in power.)

The Tessco website shwos the values of several different types of cable.

http://www.tessco.com/products/productHierarchy.do?subtabId=Braided+Coaxial+Cable+%26+Conn
ectors

other than that, I am not familiar with Tessco.

6942. 1/2 wave 11m antenna mod

Yahoo group: ham-antennas (2008)
Date: 2008-11-26 14:47:36 UTC
From: Doug
Topic: 6942 Message: 6942

Hello group,
Thought I'd take some time and give you an update on the antenna. I removed the coil at the bottom of the antenna and soldered the SO239 direct as instructed. Adjusted the vertical element to 1/4 wave of 14.300 MHZ as that is the part of the band that I use the most. I'm not using the radials as orignally planned. What I did instead is insulate the top of the mast so the antenna doesn't come into contact with it and strung a 1/4 length of wire down from the base of the antenna and
away from the mast at about a 20 degree angle. So I think I made a 1/2 wave vertical dipole. Works really well on 20m without a tuner, and 80m & 40m with the tuner. Quick question; do I need to put an RF choke at the base of the antenna? Any questions, comments or concerns are sincerely appreciated.

Cheers!

Doug...

3db? That's half of one S-unit. That may only matter if you are tring to dig a station out of the mud (noise). There is no need to be 40db over S-9 when S-5 is perfectly copyable if is above the noise. All that being said because of the wire getting sun, put underground, etc. I would buy the best cable you could afford. If you have time to play use what you have and see how it works.

>>> Quick question; do I need to put an RF choke at the base of the antenna

Yes, do that Doug.

I would also advise you to add another radial 180 degrees opposite the other one just to balance the far-field plot. Your RF will be slightly tilted towards the single radial currently which you could correct with addition of second one. Sounds a nice easy way of having a q/wave on 20m.

I don☐t think your antenna will work very well on 80m, but I☐d be interested in what happens with 40m? Please advise how long and what type of coax you are using..?

Cheers,

Callum McCormick

Subject: [ham-antennas] 1/2 wave 11m antenna mod

Hello group,
Thought I'd take some time and give you an update on the antenna. I removed the coil at the bottom of the antenna and soldered the SO239 direct as instructed. Adjusted the vertical element to 1/4 wave of 14.300 MHZ as that is the part of the band that I use the most. I'm not using the radials as orignally planned. What I did instead is insulate the top of the mast so the antenna doesn't come into contact with it and strung a 1/4 length of wire down from the base of the antenna and
away from the mast at about a 20 degree angle. So I think I made a 1/2 wave vertical dipole. Works really well on 20m without a tuner, and 80m & 40m with the tuner. Quick question; do I need to put an RF choke at the base of the antenna? Any questions, comments or concerns are sincerely appreciated.

Cheers!

Doug...

How much loss,if any, would I have if I place my tuner in my shack rather than have a remote tuner at my antenna base. The run is around 25 feet from the antenna to the shack. I have a 40ft vertical with a 1:1 balun on it.

Thanks
Rick/WA6ES

Thanks for replying Callum,
?
I'll add the RF choke and the extra radial opposite the other.? Would adding ones at 80m & 40m q/wave help the antenna operate on those bands?? I checked into the ONTARS NET As far as coax is concerned I'm running 140' of RG8X just lying on the ground for now.

Subject: [ham-antennas] Re: Recommendations for Long Coax Run

I appreciate all the advice and if it weren't for the metal roof and having to bury at least a portion of the cable, I'd go with ladder line because of low loss. Perhaps I could run coax across the roof and buried portion (about 100 feet) then the rest of the 260 feet could be ladder line? I'm not sure how that would work, whether I could just hook up coax to ladder line, etc but I'd be interested if anyone has used both in the same run to the antenna.

Thanks.

dear doug
so it is a cheap way to make an old cb-antenna to work as a quarterwave for
20
.... you did what a said you should do :-)
brave ham (grin)
if you wanna make it better ad 2 or 3 radials to build up a real vertical
not a vertikal dipole
you should ad a choke (some winding of caox will do it)
if you can get some more or similar antennas on a rally or hamfest buy them
and make the same for
17 or 15m ....
make it longer with an extension and let the coil in (maybe ad a few turns
and you have a halfwave for 12m
shorten it a bit and use it for 10m
there are many ways of using old antennas from cb-days .... :-)
cu on the bands

You only need 2 raised radials to make these work effectively, not three or four as some people think. If you really want it to work on 40m, then you ought to have a tuner at the feedpoint and yes, have tuned radials for 40m too. Still, I'm extremely dubious about this working on 80m, however I have never tried it. Anything I have ever built for 20m is deaf as a post on 80m.

Here's a bit of controversy for you: through experimentation, my friend and have made a few verticals over the last couple of years, some with tuned radials per band, others with lots of any old random radials. Untuned antennas were fed at the feedpoint with an SG230, feedpoint coupler so that 1:1 SWR was presented to the radio. We discovered that tuned radials worked better, however of course 80m and 160m radials were out the question for the very low bands. In these cases, we needed lots of random radials (always elevated). Of interest, I have a 12m vertical (40 feet) in the garden with tuned radials for 40m, 20m, 17m, 15m and 12m. However it works very quite well on 160m due to the large number of small radials.

See here: http://www.m0mcx.co.uk/?p=135

Interested in elevated radials..? See here: http://www.m0mcx.co.uk/?p=100

Hi Callum,

I didn't think it was going to work on 80m. Decided to give it a try and after tuning it I was able to check in to the ONTARS Net on 3.755 Mhz and actually carried on a little conversation with the net controller. Prior to this I was mostly unsuccessful. What is this SG230 you speak of?

Cheers!

You could always use a magnetic loop antenna. A 3ft diameter loop will work well on 20-10m and could be placed on the window sill when you need to use it.

For more information see http://www.magneticloopantenna.com

I dont think baluns are needed ... its like twinlead that you can bury or set on metal roofs etc.

Ladder line would have even less loss .. and even home brew would be better over real long run ... 2000' ... 2' space lets say ...
i dont have that kind of need ... yet. But it has crossed my mind in the past (if i move out into the sticks)

Thanks for the help and reply Sigi!

Did as you said and I'm extremely pleased. I feel like a real ham now, homebrewed an HF antenna and it actually works! Only 1 problem left to overcome, my wife hates it, says it's too tall, wants to pull it down when I'm not looking! Ha! Ha! I told her if she doesn't watch out a 70 foot tower is going up with some stacked Yagi's on it! Ha! Ha! Again thanks for your help...73...

Cheers!
Doug...

In the ARRL Antenna Handbook it suggests that it would be fine as long as the separation from the conductive roof (etc.) is at least 2 1/2 times the spacing of the "ladder line". I have used home brew parallel feed line for over 50 years and it goes up the side of my metal tower--but, it is spaced about 4 times the width of my feed line. Works fine.

Topic: 6923 Message: 6959

It won't work. The electromagnetic lines go through PVC and will be impaired by the proximity of the surrounds. Remember those TV standoff insulators of long ago?

Exactly, it has to be spaced away from conductive roof and the ground.

I don't think it will make a difference with a 1:1 balun. You have the same currents and losses eitehr way.

Before I try an answer , is the 40ft vert just a alum pole to be used on different bands?? If it is to be used as a mulit band antenna then the tuner need to be at the base , if it is at the transmitter then the coax run becomes part of the antenna and you can get more losses depending how the coax is run.

Rich , KDØZZ

Subject: [ham-antennas] Tuner Location

How much loss,if any, would I have if I place my tuner in my shack rather than have a remote tuner at my antenna base. The run is around 25 feet from the antenna to the shack. I have a 40ft vertical with a 1:1 balun on it.

Thanks

dear doug
callum made it a multiband vertical with an autotuner direct at the base
(sgc230 is one)
they were cheap and you can tune your vertical on almost any band BUT can
only handle 100w
there is an autotuner for 500w but it is not so cheap :-)
or you can look for an "aag100" autotuner on a hamfest
it can handle legal limit
it is a military device made for 100w but the components are big enough for
a "gallon"
glad to hear that all worked good for you
if your wife doesn´t love the antenna push her to make a license "grin"

Hi Callum,

I didn't think it was going to work on 80m. Decided to give it a try and
after tuning it I was able to check in to the ONTARS Net on 3.755 Mhz and
actually carried on a little conversation with the net controller. Prior to
this I was mostly unsuccessful. What is this SG230 you speak of?

Cheers!

OK , now think of that as ½ of a dipole , it will be good at about 5.85Mhz anywhere else and you will need capacitance , inductance or both to get it resonate , it will make a 5/8 wave for the20m band.

I would not recommend it without a tuner at the base, or a remote relay system for the bands you want.

I Have the DX Engineering 43' multiband vertical. All it is is a series of tapered aluminum poles. They recommend a 4:1 balum at the base and a good tuner in the shack. They claim (and I tend to believe them more than most based on past experieinces with their tech people) that the loss is very low. I put up about sixty radials each 70' long and this vertical is outperforming my old Hustler 6-BTV by many dB based on new range of DX contacts and signal reports. Plus I painted the vertical (non-metallic paint) in a camo pattern and it is vitually invisible to anyone beyond my 1/2 acre property line.

Hi, Rod. Two meters should be EASY on a motorcycle. I've seen all the recommendations for no-ground-plane antennas, but if you have a luggage rack, run down to a truck stop and get a mirror-mount for a 3/8"X24 CB antenna. These mounts will bolt to a tubular luggage rack just fine. You then have the option of using an actual 3/8"X24 2-meter antenna, like the Hustler SF-2, seen at <http://www.universal-radio.com/catalog/hamantm/1999.html> -- or you can remove the 3/8"X24 hardware, drill out the plate and install an SO-239 "bullet" and run something like a Comet SB-15 that mounts on a "UHF" mont -- see one at <http://www.universal-radio.com/catalog/hamantm/1167.html>

As for a ground plane -- well, years ago I mounted a Hustler HF antenna on the crash bars of my 1977 Gold Wing and worked all over the world with it, and most of the guys I worked were just incredulous that I was on a motorcycle, until I keyed the mic and revved the engine. The crash bars and frame of the bike were enough for 20 meters, and a luggage rack will work on 2-meters -- I've done that, too. Unfortunately haven't had a bike for about 10 years now, maybe have another one day.

6972. G5RV

Yahoo group: ham-antennas (2008)
Date: 2008-11-28 02:45:09 UTC
From: al_kozakiewicz
Topic: 565 Message: 6972

Some background: I'm returning to ham radio after a 35 year hiatus. I was in a hurry to get on the air. To make a long story short, I bought a commercial (MFJ) G5RV antenna mainly because I had two very convenient trees 110' apart and the centerpoint of the antenna ended up about 10' from the corner of the house where my shack is. The rig is an old Kenwood TS-820S with an AT-200 tuner. The antenna is fed with RG-8U and an air choke I created by winding abou 20' of the coax around a piece of 4" PVC pipe. The wire is only about 20-25' up.

I _know_ the G5RV is a compromise antenna. It looks like the bands I want to operate on mostly are 80 and 20. Most of the time I get to dedicate to the hobby are evenings and every band is dead then except 80 and 160. 20 has activity during the day, which works for me on weekends. The antenna seems to be OK on that band, though the SWR never drops below 3:1 anwhere in the band without the tuner. 40 seems hopeless at night with all the SW stations every 20 kHz or so.

I'm planning to put up some 'real' antennas soon. I'm thinking of an inverted V for 80, or maybe a delta loop that will fit in the same footprint and could work on 40 and possibly 160 as well. I'm not sure about the supports I have available that don't involve a long feedline and whether I can get the center up to the 55' that seems to be optimal. For 20, I'm thinking about a compact 2 element yagi that I can mount to the house with a rotator that won't be conspicuous from the street.

Anyway, back to the G5RV. I spent about 5 hours operating in the ARRL sweepstakes contest a few weeks ago in order to gauge what I can do with the current setup. I managed to work 37 sections, including the Virgin Islands and the west coast, and mostly on 80, so the thing isn't totally useless.

Here's the thing that has me puzzled and annoyed. There's an informal group that operates just below the 80m DX window late most nights, around 3787. QTH's range from England to Florida. Most are running beams on towers and legal limit amplifiers. I can make contact with most, but they can usually barely hear me. I'm hoping the inverted V and a linear will improve on that.

I also like to participate on a regional net that operates on 3872. The net control most nights is a ham that is located less than 20 miles away and usually HE CAN'T HEAR ME AT ALL!!! I can't figure that one out to save my life! Does my antenna have some unusual characteristic that prevents it from radiating at that frequency? I did have to add a 10' patch cord to the feedline in order to get the (tuned) SWR down from a 3:1 to below 2:1 on 80. Does that indicate

some wierd problem?

Any comments would be appreciated!

Regards,

Al
AB2ZY

Topic: 565 Message: 6973

Al,

I've used a G5RV for over a decade. The G5RV likes 80 and 40 better than 15 and 20. Still, several times I've worked nearly a thousand miles with a 75mw homebrew rig and the old G5RV.

If I were you I would start unwinding the air choke a turn at a time and see if there's a point where the SWRs improve. That SWR should go to 1:1 without much troubke. If that doesn't help pull it down and be sure everything is securly soldered at the apex. Be sure you coax between the tuner and your radio is good. I certainly wouldn't give up. The G5RV is one of the most forgiving antennas I can think of.

Today I worked Oak Harbor, WA with 4 watts and MN with 5.

Keep us posted.

I suspect an actual dipole or inverted-V will make a big difference
here. If you hang it low -- maybe 20' up -- you'll get basically
omnidirectional coverage with a high angle of radiation -- think NVIS.
Probably about right for a net like you're thinking of.

Sounds to me like he's in your skip zone. Do others on that same
net hear you?
> Does my antenna have some unusual

What that indicates to me is that the antenna isn't really working
that well, and that extra coax is acting as an impedance transformer to
make your rig happy. I think an actual dipole or inverted-V will
operate a whole lot better in this case.

Just my 2 cents: For a year I used an MFJ G5RV with very little success, yes I made contacts and had some fun but just nothing worth bragging about, I then installed an Alpha Delta DC-CC dipole
and the world opened up. I'll never use a G5RV again. Nothing against MFJ, I use plenty of their accessories with great success.

The RG-8U coax is brand new, bought from a local supplier who's been in business for 50 years. Cost nearly a buck a foot...ouch! I would have used RG-8x if they had it, but I was in a hurry...

I thought the G5RV was resonant on 20m and expected the antenna to exhibit something approaching the "ideal" 1.8:1 SWR without a tuner. Beyond not being able to establish a QSO with a guy 20 miles away, that's the main thing that got me thinking something is wrong.

Since it's a manufactured antenna and it's less than a month old, I wouldn't think connections would be a problem, but I'll check anyway.

Why do you think removing turns from the choke would help?

Thanks and regards,

Al

To varying degrees, yes, but it's not universal. In one of the more absurd examples, a ham in MD (I'm located near Albany NY) was relaying a summary of my conversation to the net control guy 20 miles away from me. Based on how many of the details he got wrong, I suspect he wasn't hearing me very well either. It seems to be something about that end of the 75m band. When I operating in the extra class segment I seem to get better results. That observation, by the way, is completely anecdotal.

I know that at 80m and the relatively low height, the antenna going to be omnidirectional and have a high radiation angle, but shouldn't I still have something of a ground wave for 20 miles?

Thanks and regards,

Al

There is a world of difference from the MFJ G5RV and one made from the original spec, and even one made to the modified spec. (look on google) Mine is 102 feet long, fed in the center with 450 Ohm window line, not twin lead. The feed line is 38 feet long, and no balun or choke needed. I used one made this way for field day this past summer. The apex was at 39 feet, and I used only 25 feet of LMR400 coax to the RV. We ran only 5 watts SSB, and made over 150 contacts. Keep in mind, my health problems only let me operate 2-3 hours on, and then I had to rest. Yes, it is a compromise antenna, but not a bad compromise. I used it on 75, 40 and 20 meters with an MFJ antenna tuner.

You are right, if it isn't working on 20, then something IS wrong.

6980. Re: G5RV

Yahoo group: ham-antennas (2008)
Date: 2008-11-28 05:28:31 UTC
From: Scott Laughlin
Topic: 565 Message: 6980

Al,

I don't know that removing turns off the choke would help, but it might help. I've made several 2m J-poles that had erratic SWRs and putting a choke in the feed line, adding and subtracting turns until they settled down. It might work on your HF antenna.

I made a choke for my G5RV of six turns in about a six inch loop.

Where the twin lead changes to coax there might be a balun. It might be in a section of pvc about six inches long with caps on the ends. Be sure the holes are sealed.

If there isn't a balun in the line you might try letting the legs droop until the apex makes a 90 degree angle between the legs and then bring the lead straight down.

I suggested looking at the connections because I've heard at least one rumor of a MFJ antenna having connections that the solder person missed.

Before you give up go to the designer's web site.

http://www.astrosurf.com/luxorion/qsl-g5rv.htm

and see if there's something in there that will help solve the problem.

If all that fails I would contact whomever you bought the antenna from. I've found that working directly with MFJ is a very slow process.

All these steps shouldn't cost any money. I just hope I'm not making you waste your time.

Scott,

I'm the absolute master at wasting my own time, so please don't worry about it ;^)

The MFJ antenna is pretty straightforward - 102', center fed with 34' (or whatever length the matching section is) of window line and terminated with an SO-239. No balun.

I just double checked. At 14.150 mHz with the tuner switched OUT, the SWR is 4:1. At 14.350, it's basically the same. It drops to 3:1 at 14.030. I'm measuring SWR at the tuner in the shack. If the consensus is that that is a problem, then at least I have a way to tell if I'm making an improvement as I troubleshoot.

Maybe, although I know that 35 miles is totally out of the question, from experience years ago.

As for the G5RV -- I've never used one, but it sure sounds to me as if a dipole tunes up a lot easier! :-)

I've been looking through the ARRL Wire Antenna Classics book. I've got a decent sized lot, but none of my trees seem to be in "right" location or of the "right" height to build a bunch of single purpose antennas.

At any rate, does anyone have any experience with something called the Loop Skywire? It's basically a full wavelength antenna folded into a square and fed directly with coax. It promises multiband operation (integral harmonics of the base design), low noise and a takeoff angle like a vertical. If it sounds too good to be true.....

If I use the house as one of the supports, I can probably fit this in the corner of the yard that's most conducive to antenna construction.

From: Bill
Topic: 565 Message: 6989

Hi Al
I used a G5RV for several years and finally abandoned it for a Super Loop. One thing to remember is that the G5RV will always have a high SWR and that is the reason for the extended length of the coaxial feedline. By utilizing the long coax the SWR at the interface is reduced substantially at the tranceiver.

After trying to get one to work for me I redesigned it to about 92 feet and used my Antenna Analyzer to cut the window wire to a length that worked well on both 40 and 80 meters. I did not use it on 20, though since I have 5 element beam for that band.

My 40/80 meter super loop is about the same overall length but requires a bit more height perhaps since the vertex is well below the horizontal section. It works well on 20 and the other bands, though, much better than the G5RV ever did.

All in all the G5RV is a very compromised antenna that should only be used where nothing else will fit (IMHO).

From: Callum M0MCX
Topic: 6985 Message: 6990

Al,

That□s my bag. You are right in your analysis. Use a 4:1 balun and coax to the shack for multi-band use. I have three up at the moment and on my smaller 40m one, have worked right around the globe on both 40m and 20m. It□s only 20 feet up.

One last bit of □new□ information that you won□t find on the internet is that if you build these in an equilateral triangle, you□ll get some gain forming opposite the feedpoint in the higher bands. Very interesting. We call it the XXT loop.

There□s loads of info on large loops on my website. Also check out the picture sections, I have more there.

Cheers,

Callum McCormick

Subject: [ham-antennas] Loop Skywire?

I've been looking through the ARRL Wire Antenna Classics book. I've got a decent sized lot, but none of my trees seem to be in "right" location or of the "right" height to build a bunch of single purpose antennas.

At any rate, does anyone have any experience with something called the Loop Skywire? It's basically a full wavelength antenna folded into a square and fed directly with coax. It promises multiband operation (integral harmonics of the base design), low noise and a takeoff angle like a vertical. If it sounds too good to be true.....

If I use the house as one of the supports, I can probably fit this in the corner of the yard that's most conducive to antenna construction.

Scott,
The G5RV is designed as a gain antenna for 20 meters and is a compromise on 80 - not too shabby on 40 though. But if it works better on 8o than it does 20 meters, then something is wrong. I know a ham that has one up at a remote cabin and consistantly works DX on 20 & 15 meters on it using an old Yaesu FT-7 at 10 watts. The G5RV should work great on those bands, if it doesn't I would suspect a problem somewhere.

John,
Switching to a wire antenna won't help much becuase most wire antennas are horizontal and so is the power lines. I have the same problem here. If you have a rig that will do 2 meter AM mode, take it out and drive around and you will find the problem area as you drive by the pole causing the problem. Once you find the area its coming from, turn the RF gain down to attenuate the signal and then drive around that area to zero in on the problem then writhe down the pole number its coming from. If you have a scope or even a soundcard interface and spectran software, check to see if the signal is 120hz - if it is, then it is in fact AC power line noise. The AC is 60 cycles, and the 120 cycle signal comes from the combination of the 60 cycle postitive and negative peaks and you will be able to see it on a scope or using the spectran software and your psk interface you can spot it easily. Also llok around at night for faulty street lights - flickering streetlights will cause horrible noise ! Report any of your findings to the power company.

Good luck !

Jerry,
If you are feeding it with coax then the losses will only be low on its resonant frequency unless you put a tuner at the feepoint for multiband operation. But as swr rises on coax, so does the losses. I tend NOT to believe what most antenna manufacturers tell me and believe known laws of physics. The antenna sellers just want your money !

The SWR on a G5RV on 20 meters should be around 1.8:1 - not 4:1 !

Rick,

There are many things that contribute to how well an antenna functions. I'm not surprised your friend does so well at his remote cabin. He probably doesn't have to deal with a city council and a swimming pool. In spite of my nay sayers and obsticles, this G5RV has done me proud on QRPp. I'm 150 miles shy of my 1000-miles-per-watt certificate on 20. As conditions improve I'll get it earned.

The G5RV has dramatically different patterns depending on what frequency you're operating on. I've run EZNEC+5 with the G5RV model provided with the ARRL Antenna book on 80 meters (3.6MHz) and 20 meters (14.250MHz) and at 20 meters you have some major nulls show up. Your takeoff angle for the major lobe is much lower too (10 degrees at 20 meters compared to 39 degrees at 80).

I've combined the printouts into one file and have uploaded it to the groups files section. You can look at it here:

http://f1.grp.yahoofs.com/v1/0FswSZkGkwNrtmvogZ9kWnfwALcMGuhNgyKq2mDuuomp1BI4pvNDpqjDwlFX7Y4FuYBFogU7jreUQeGrOICZHFst453YgGlL/G5RV-Model.pdf

I agree with Rick 100% KC8AON, it would work best with the tuner at the base.

*** this is what I sent to WA6ES about his. If it is to be used as a mulit band antenna then the tuner need to be at the base , if it is at the transmitter then the coax run becomes part of the antenna and you can get more losses depending how the coax is run

Don□t get mixed up but all three of us have the same first name, I am glad we added a Jerry.

Rich , KDØZZ

Subject: [ham-antennas] Re: Tuner Location

Jerry,
If you are feeding it with coax then the losses will only be low on its resonant frequency unless you put a tuner at the feepoint for multiband operation. But as swr rises on coax, so does the losses.
I tend NOT to believe what most antenna manufacturers tell me and believe known laws of physics. The antenna sellers just want your money !

Yeah good point Rick

I too use a G5RV and tuner. The instruction also include a tuner. The ladder line needs to be almost 90 degrees to the dipole wire and not on the ground. That means the antenna needs to be up 30 feet.

Callum,

I just spent an enjoyable hour browsing your website. Did you know that you Brits write just like you talk? ;^)

Weather and wife permitting, I'm going to put up a loop this weekend. The ARRL article from November 1985 was quite clear that you could feed the thing directly with coax without a balun and that a transmatch (a.k.a. tuner) would clean up any mismatch. What's your opinion?

Also, most everything I read speaks glowingly of the DX possibilities, but it's not clear to me what the radiation angle is supposed to be. Vertical? Low?

Regards,

Al

I agree with this statement below 100%. I've been telling as many hams as I possibly can, over the years. I've seen this love affair for the G5RV finally start to dwindle. It is an antenna designed for the "tube transmitter" days, when 3:1 SWRs were OK, and... when tuners were not a part of our radios. Now we have rigs that cannot tolerate such a high SWR. Keep in mind that the higher the SWR, the greater the losses with coax. With the G5RV, the matching system built into this system has tremendous losses, especially above 30 meters.

I have not been able to determine why this antenna was favored over a ladder line fed dipole, which has tons less loss. People claim that it outperform a dipole, but the G5RV IS a dipole with a matching section. IF you need to run your G5RV with a tuner, for the new rigs, then you are MUCH better off with a ladder line fed dipole. It will output perform the G5RV any day, AND THERE IS NO HYPE IN THIS MESSAGE.

But the best scenario, by far, is a properly fed, properly matched antenna that does not need a tuner at all. Get the radiation TO the antenna and don't lose the power in the feed line. Get rid of your G5RVs. They were perhaps acceptable once, when tuners were more expensive and we were running tube transmitters. They are no longer a good solution. They are lossy and a waste.

Subject: Re: [ham-antennas] Re: G5RV

Hi Al
I used a G5RV for several years and finally abandoned it for a Super Loop. One thing to remember is that the G5RV will always have a high SWR and that is the reason for the extended length of the coaxial feedline. By utilizing the long coax the SWR at the interface is reduced substantially at the tranceiver.

After trying to get one to work for me I redesigned it to about 92 feet and used my Antenna Analyzer to cut the window wire to a length that worked well on both 40 and 80 meters. I did not use it on 20, though since I have 5 element beam for that band.

My 40/80 meter super loop is about the same overall length but requires a bit more height perhaps since the vertex is well below the horizontal section. It works well on 20 and the other bands, though, much better than the G5RV ever did.

All in all the G5RV is a very compromised antenna that should only be used where nothing else will fit (IMHO).

Scott,

I'm the absolute master at wasting my own time, so please don't worry about it ;^)

The MFJ antenna is pretty straightforward - 102', center fed with 34' (or whatever length the matching section is) of window line and terminated with an SO-239. No balun.

I just double checked. At 14.150 mHz with the tuner switched OUT, the SWR is 4:1. At 14.350, it's basically the same. It drops to 3:1 at 14.030. I'm measuring SWR at the tuner in the shack. If the consensus is that that is a problem, then at least I have a way to tell if I'm making an improvement as I troubleshoot.

>
A center fed dipole does work better on the fundamental, and odd harmonics. But, it will not work on even harmonics. That is the reason the G5RV is so popular. For example, a 40 meter dipole will not work on 20 meters, but is excellent on 15 meters. But take the same wire, 1/2 40 meters and off-center feed it, and now it works on even harmonics, but not odd. The G5RV overcomes this by not being resonant. This is great for those that can only put up one (1) antenna for HF. It might not be the best radiator, but sure beats fighting with the landlord to put up more than 1 wire.

> But the best scenario, by far, is a properly fed, properly matched antenna that does not need a tuner at all. Get the radiation TO the antenna and don't lose the power in the feed line. >
Actually, the losses are minimal. The length of 450 or 300 ohm feed line is not so high as to keep the antenna from radiating. Even if the SWR is 10:1, which it typically closer to 5 or 6 to one worst case.

The point is, not everyone can put up a 100 foot tall tower, and can hang all the wire they want to. I use a G5RV for the RV with a 40' pole as a center support. I do this so I can have all HF bands with minimum fuss when travelling. I can go to almost any RV park and get away with stringing one wire. Can you imagine the fuss if I tried to put up a 3 element beam on a 50 foot tower? Not to mention the logistics of carrying one while driving down the highway.

Hi Matt , I was looking at you note , looking for an antenna. Neil, G7AQK has a good idea on making a loop. I followed that lead and found one by N3KZN, John Gbur. http://www.dxzone.com/cgi-bin/dir/jump2.cgi?ID=9868

I am so impressed by the looks of his antenna in part III . That octagon , PVC antenna set up will also be a wonderful ☐show and tell☐ demo in the local park for field day. Matt you could slip it out at night or by a window in daylight and work your band.

Thanks to you Neil for reminding me of the loop,

Rich , KDØZZ

You could always use a magnetic loop antenna. A 3ft diameter loop will work well on 20-10m and could be placed on the window sill when you need to use it.

For more information see http://www.magneticloopantenna.com

You can find ref to this as a ☐LATTIN☐ antenna.

7010. 20M Wide Band Vertical

Yahoo group: ham-antennas (2008)
Date: 2008-11-29 16:40:36 UTC
From: Richard Schmuke
Topic: 7010 Message: 7010

I just mounted my 20M wide band vertical on my small tilt up mount. Feed point is elevated about 21ft. SWR is very good both on PSK-31 and SSB operating area. I uploaded a rough sketch of the antenna .

>Actually, the losses are minimal. The length of 450 or 300 ohm feed line is not so high as to keep the antenna from radiating. Even if the SWR is 10:1, which it typically closer to 5 or 6 to one worst case.<

Although the losses tend to be somewhat small they are not negligible. Moreover it is not the loss in the balanced feedlline that is the issue. It is the loss in the coax which is recommended to be 70 feet or more to ameliorate the SWR at the transceiver. Even on 20 meters there can be as much as 15 watts of loss in the coax depending on how well the impedance is matched at the end of the balanced feedline.

Having said that I used my modified G5RV very successfully on 40 and 80 meters recognizing that it was nevertheless a compromised antenna. Since I did not need it on 20 (5 element monobander) 15 or 10 (4 element tribander) it did not mean much to me to use it anywhere else except sometimes on the WARC bands. I have replaced it with two Super Loops, one for 40/80 and a second for 30/60 meters. They take about the same horizontal space as the G5RV but must be high enough to raise the vertex a reasonable distance off the ground. The impedance at the source is 200 +j0 for both of them at the source on the upper band of each of them and do not require a tuner. (Height of both is 85 feet).

As I said before, the G5RV is a compromise for those who simply do not have the room for anything else. As such it is a good choice for many who simply cannot do anything else although there are many who will argue that the Carolina Windom is better.

rigs, then you are MUCH better off with a ladder line fed dipole. It will output perform the G5RV any day, AND THERE IS NO HYPE IN THIS MESSAGE.
>
A center fed dipole does work better on the fundamental, and odd harmonics. But, it will not work on even harmonics. That is the reason the G5RV is so popular. For example, a 40 meter dipole will not work on 20 meters, but is excellent on 15 meters. But take the same wire, 1/2 40 meters and off-center feed it, and now it works on even harmonics, but not odd. The G5RV overcomes this by not being resonant. This is great for those that can only put up one (1) antenna for HF. It might not be the best radiator, but sure beats fighting with the landlord to put up more than 1 wire.

> But the best scenario, by far, is a properly fed, properly matched antenna that does not need a tuner at all. Get the radiation TO the antenna and don't lose the power in the feed line. Get rid of your G5RVs. They were perhaps acceptable once, when tuners were more expensive and we were running tube transmitters. They are no longer a good solution. They are lossy and a waste.

Actually, the losses are minimal. The length of 450 or 300 ohm feed line is not so high as to keep the antenna from radiating. Even if the SWR is 10:1, which it typically closer to 5 or 6 to one worst case.

The point is, not everyone can put up a 100 foot tall tower, and can hang all the wire they want to. I use a G5RV for the RV with a 40' pole as a center support. I do this so I can have all HF bands with minimum fuss when travelling. I can go to almost any RV park and get away with stringing one wire. Can you imagine the fuss if I tried to put up a 3 element beam on a 50 foot tower? Not to mention the logistics of carrying one while driving down the highway.

I see two small problems with building this for 5 bands. First is normal twin lead won☐t be strong enough for a 80M set up in bad weather. If you fix that problem then remember to tune 80M first then 40 , next 20 and so on as there might be interaction with the stubs . I made a 5 band fan dipole and the first time made the mistake of starting with 10m not 80, when tuning. I used copper-weld for the 80 for better support, regular copper for the other bands.

LOL Well, 15% is negligable when at 75% loss, you only loose 1 "S" unit. Sort of like the argument of "I gotta have 1500 watts out cuz 1200 ain't enough"! :-)

For the guy limited to putting up one wire only, it is better than no antenna.

The Carolina antenna does suffer from the Even harmonic problem, though. It is an OCF dipole. And the Balun is subject to it's own problems (Saturation, heating, arcing etc.) that the G5RV doesn't have.

If I had the room, I would like to put up one wire antenna, it would be a rhombic, minimum of 450' per leg, 3 curtains, terminated. LOL If my health was better, I'd even settle for 4 stacked tribanders. Just day dreaming.

Steve/WM5Z
Just because you say I'm paranoid doesn't mean they aren't watching us.

Gentlemen,

There is a passion for the G5RV. But there are some facts here that you must consider, and you can research this on your own. Don't take my word for it. Open up an ARRL Antenna book. Open up a "Low Band DXing" book. Read the information on coaxial loss. As you climb in frequency, even WITH a good SWR, you have more loss. This is all fact, no hype.

And the further away from resonance, the worse the losses. Look it up for yourself. With the G5RV, the coax is used as part of the the match, which means that the loss are higher with a G5RV. The antenna is designed this way. And I know that "high" is relative, but this is for sure, the losses in the coax with a G5RV are much higher than a dipole using ladder line. Look it up for yourself and do youself the favor. Simply do the math.

I also heard the comment that for limited space... Well, for limited space, you can still use a tuner with ladder line. I myself, use a ladder line fed, 100 foot dipole, with an AH-4 at the base. It tunes from 160m through 6m. It outperforms a G5RV. No doubt. And I've visited several websites of many experts who have analyzed the G5RV. It does help you to get the tuner to tune properly, since it can bring the antenna to a closer match. But you are giving up something when doing this. But it makes no sense at all that if you are using a tuner, then why would you use a G5RV? It certainly would not perform as well, this has been proven time and time again.

By far, the best situation is a tuned antenna to limit losses. If you do not have a tuned antenna, then the next best thing is using low loss ladder line. Then from there, you can consider a G5RV, but it will not perform as well as a tuned antenna or a dipole using ladder line.

W8OKN

Get rid of your G5RVs. They were perhaps acceptable once, when tuners were more expensive and we were running tube transmitters. They are no longer a good solution. They are lossy and a waste.

One thing to remember is that the G5RV will always have a high SWR and that is the reason for the extended length of the coaxial feedline. By utilizing the long coax the SWR at the interface is reduced substantially at the tranceiver.
> >

7017. Cushcraft R7 Problem

Yahoo group: ham-antennas (2008)
Date: 2008-11-29 22:21:46 UTC
From: markswoodcrafts
Topic: 7017 Message: 7017

I bought an R7 at an auction recently and have been having SWR problems. It is on all bands. What happens is when I initially load, with only 10 watts, the SWR is low. Then when I increase power just a bit, the SWR shoots to infinity.

I have replaced the two 80pf caps with 50pf doorknob 7.5kv one, plus the 27pf cap. I don't really see any trouble with any of the traps, since this problem effects all bands.

The toroids look good in the matchbox as well.

I also checked the coax and it is fine.

Any ideas?

Mark KØITC

none of your traps are upsisde down are they? or you are not getting a good ground or sound like you may have a lose connection. might check all your meserments to.

[snip]

While its true that the losses on the balanced feedline are low, but
then its connected to a 70' hunk of lossy coax and you simply cannot
ignore that fact ! On 20 meters where the G5RV is designed for the
losses will be fairly low, but as you move away from the design
frequency (and yes, the G5RV was designed as a RESONANT antenna for
20), the swr will rise and so will the losses. To improve the
performance on several bands with the G5RV, simply skip the coax
section and run low loss balanced feedline all the way to the shack -
the increased efficiency will astound you !

Your assumption above is wrong. I do NOT have 70 feet of lossy coax. I have 25', but at this junction is where I am using an auto tuner. So, the losses through my coax are very minimal. Then I also am using LMR400, but that is simply because of what I have. What you describe below is simply not a dipole either if you maintain the 102' length.

Here is where everyone is running around, shouting fire in the theatre, If the antenna is lengthened to make it a center fed dipole, then on even harmonics, it doesn't work. This means that if the wires are 135' or there abouts, then you wind up with 1/4 wave lengths at 80/75 meters, and this is good. It will have a feed point impedance of close to 50 ohms, depending on how high you mount it from ground. At the height of 35-40 feet, depending on the quality of the earth, you will likely see 35 ohms. Try to load this same antenna on 40 meters now, and you have a problem. Now each leg is 1/2 wavelength, and the feed point is sky high, probably close to 5,000 ohms, again the exact amount will be dependant on the environment. This antenna is indeed still resonant, just not usable. Go up to 10.5 Mhz, and the antenna again has a resonant point, and now each leg is 3/4 wave. The Z will be nice and low. It will let the transmitter feed it just fine, and with some fenagling will work on 30 meters. Now go up to 20 meters, and guess what. This antenna's SWR is again going to be high. It is still resonant, but the feed point is seeing a full wavelength on each leg, so the impedance is going to be

high again.

OK, so let's go the other way. Let us shorten each leg to 67 feet. Now it will work on 40 meters because each leg is 1/4 wavelength. But, go up to 20 meters, and each leg is now 1/2 wave length. So, just like the 80 meter dipole was on 40, now the 40 meter dipole exhibits the same characteristics. Of coarse of 21Mhz, all is fine again as each leg is now 3/4 wavelength.

What Varney did was COMPROMISE with his design so that he could, with one antenna/feedline build an antenna that could be used on any band from 80 meters through 10 meters, be it that it needed a matcher. Match boxes have been around a long time, so that isn't the problem. He added the coax using the special length he made his so that he could have the matchbox inside because his arms weren't long enough??? to put it outside.

Like I have been saying all along, the G5RV isn't such a bad antenna. I use one for the RV because it is simple, quick to install, does radiate a reasonable percentage of the transmitter power and with an automatic tuner is reasonably transparent while operating. Are there better antenna? Of coarse. At home, I use a Fan array of loaded dipoles that give me 160, 80, 75, 60, 40 and 30 meters. But it would be a PITA to take and set up while camping. Especially trying to maintain 60 feet at both ends at a resort or camp ground. For those that are struggling with covenants and land use restrictions, it might be the only way they could get on more than one or two bands.

In a head to head contest, I will use my G5RV over the screwdriver antenna while camping any day. I see a minimum of 3 'S' units on any band and on 80 meters, I see as much as 30dB difference. Been there and done that. It is also easier than my other method which uses the internet to connect back to home to get on the air. There is never an internet connection when I want one. ;-)

Steve/WM5Z
Just because you say I'm paranoid doesn't mean they aren't watching us.

That's partly true. When I built mine, I used the 450 ohm window line.
But also don't use RG58 for the coax. Even the 8X coax is pretty lossy.
You can usually find some hard line or LMR400 at a swapmeet or hamfest.
This would be best.

Thanks. That should work pretty work pretty well if I add some additional fiberglass "elements" to give it more of the shape of a typical TV antenna.

Topic: 6985 Message: 7024

Well, I took down the G5RV today and put up a 265' loop. It's the ugliest antenna I've ever seen. Because of my non-strategically located trees, the thing is 6 sided, a bit oblong at one end and one of the supports is no more than 15' above the ground.

I fed it directly with RG-8U, undoubtedly cold soldered as I didn't start until about 2 hours before sundown and I was attaching the feedline in the dark. I found the element on the soldering gun had opened up sometime during the process when I got it back inside.

The thing matches (tunes) much better than the G5RV ever did. It's naturally resonant without the tuner at the low end of 80m, around 3.6. I was shooting for 3.8, but at least it isn't too short. The SWR shoots up to 3:1 above 3.8, but the tuner matches it to 1:1. Receive noise is markedly lower than the antenna it replaced.

80m DX is marginally better than the G5RV (which isn't saying much), but I shouldn't expect much with the low height. I'll try it out on 20m during the day tomorrow and see what it does.

I'm still left with a problem of what to do on 80m, the band I desire good performance on the most. Wire antennas are going to be a problem for me no matter what, as I just don't have trees high enough and in the right spots to get any significant elevation to avoid the cloud burner problem.

For 80m, I guess I need to start looking at manufactured verticals. Any suggestions?

Regards,

Al

Steve,
How do you get that 67' is a 1/4 wave on 40 meters ? 67' is a 1/2 wave on 40 meters - 33' is a 1/4 wave on 40 meters ! But back to the dipole you say won't work on even harmonics - don't know where you got that info but folks have been using them on even harmonics for decades ! For example, the old standby all band antenna in all your antenna handbooks for as long as I can remember is a 135' long dipole fed in the center with low loss balanced feedline and with a tuner will work 10 thru 80 meters - I know, I used one for a few years. I now use a 40 meter expended double zepp which is 178' and center fed with 450 ohm balanced feedline and it will work 10 thru 160 meters and give me fabulous results. So saying it won't work is misleading - it may not be the best antenna or perfect, but it does work, and works quite well !

Also, on your G5RV, you are using a tuner (coupler) at the junction of the balanced feedline and coax - this is a good thing because you do eliminate most of the loss associated with the coax because the coax is being operated in a matched condition. But, by putting a tuner there, you do not have a conventional G5RV antenna - it just happens to have the same dimensions of the G5RV minus the 70' length of coax. But if you do use it in the standard configuration, the 70' of coax does have some associated losses - there is simply no way around it. I do like the way you do it though - putting the autotuner at the junction of the coax & balanced feedline is the way to go and it will work much better !

7027. G5RV analysed

Yahoo group: ham-antennas (2008)
Date: 2008-11-30 19:13:17 UTC
From: steve95446
Topic: 7027 Message: 7027

Hi,

I've been following the G5RV debate careully. My own experiments with a G5RV showed that it worked reasonably at 3.5Mhz and 7Mhz, but was not so hot on the higher bands. Please understand that the results below were as measured with an MFJ analyser in a real-life situation.

I mounted the G5RV as an inverted V at about 25 feet and the ends at about six feet. Not ideal, but this was a typical surburban (UK) installation.

I first measured the coax loss of the 30ft of RG58 feeder with an MFJ 259 analyser. I don't think this was a particularly good make of coax. The results were as follows which back up my hunch.

3.6 MHz: (0.6db)
7.1 MHz (0.7db)
14 MHz (1.3db)
21.2 MHz (1.4db)
28.5MHz (1.8db)

SWR figures were then measured at bottom of the ladder line with an MFJ 259 analyser. The figures in brackets are also the SWR as measured in the shack after the run of 30ft of RG58 - note the difference as the coax reduces the apparent SWR where it is high.

I used the calculator at:
http://www.dxzone.com/cgi-bin/dir/jump2.cgi?ID=12232

The final figure is therefore the calculated total loss taking the measured loss and SWR loss into account.

3.5MHz: 2.0 (1.7) - 0.646dB
3.6MHz: 3.0 (2.2) ☐ 0.724dB
3.8MHz: 4.2 (3.6) ☐ 0.823dB

7.0MHz: 2.2(2.2) - 0.784dB
7.1MHz: 2.4 (2.3) ☐ 0.806dB

14.150MHz: 4.5 (5.7) ☐ 1.954dB

21MHz: 3.9 (9.6) ☐ 2.83dB

28MHz: 3.6 (12.4) ☐ 3.862dB
29MHz: 3.2 (9.5) ☐ 3.397dB

So you can see how the losses build up as the frequency goes up.

As an aside, I then calculated the likely loss if you used window line all the way to the ATU. Worst case scenario of 25ft+30ft of generic window line at an SWR of 12.4 at 28MHz gave a loss of 0.405dB.

So, by turning a G5RV into a doublet, and extending the ladder line all the way to the shack, you gain about 3db at 28MHz. If you are interested in 40m and 80m it probably makes little difference.

Steve G0KYA

From: Chris
Topic: 7027 Message: 7029

Check on this site for some excellent info on optimizing a G5RV among much other great antenna related tests and data.

http://www.vk1od.net/

The article is a link near the bottom section of the page. It describes how to analyze and tune a G5RV.

7030. Re: G5RV

The G5RV was designed to be an antenna system which includes the radiating element and the feedline.

Excellent reading on Louis Varney's G5RV is to be found on www.cebik.com in L. B. Cebik's "The G5RV Antenna System Re-Visited":
Part 1: The G5RV on 20 meters
Part 2: The G5RV on all HF Bands
Part 3: The Almost-No-ATU G5RV-Type Antenna

Hi Al,

Thanks for the compliment.

Yes, you can feed without a balun but you will have currents of the outside of the current, so add some ferrite clip-ons near the feedpoint if you can. In my experience though, and contrary to recent research - the impedance can be anywhere from 65 to 250 ohms depending on the frequency so a 2:1 balun or a 4:1 balun would normally assist a match. Of course, you will need to use the radio's ATU to bring a match. Normally, you can ignore small SWR for these purposes.

Genuine DX possibilities are only achievable if you have this thing fairly high. It's just like a Yagi or dipole in this regard. The real minimum is quarter wave above ground, ideally you will need half to one wavelength above the ground for DX. I use an 160m version at 80 feet to work 80m DX and this is only just achieving lower angles. You really need 100 feet plus for DX angles at 80m wavelengths.

However, for 40m and 80m, there's nothing like building a loop just 30 feet high. It will give you excellent 500-1,000 mile fun with some DX if you push hard. I have gone around the world on my little 40m loop with 100w sometimes - and it's only 25 feet above ground. Works pretty well on 20m though and even has some directivity too.

All the above relates to horizontal loops. I don't have much experience of vertical loops. ON4UN's (?) book deals with this part of the topic well which also states that you will need a good earth for vertical delta loops. Don't believe those people who say you don't need an earth for vertical delta loops. It's like saying that you don't need an earth for a vertical. Codswallop. Anyway, I digress.

If you build it, they will come.

Callum,

I just spent an enjoyable hour browsing your website. Did you know that you Brits write just like you talk? ;^)

Weather and wife permitting, I'm going to put up a loop this weekend. The ARRL article from November 1985 was quite clear that you could feed the thing directly with coax without a balun and that a transmatch (a.k.a. tuner) would clean up any mismatch. What's your opinion?

Also, most everything I read speaks glowingly of the DX possibilities, but it's not clear to me what the radiation angle is supposed to be. Vertical? Low?

Regards,

Al

I want to see you build a dipole with 1/2 wavelength per leg, and feed
it with coax. What happens? You pick the band, the length of the coax,
but it must be long enough to reach the dipole and run to the shack.

I ordered a Butternut HF2V today. Hopefully it will arrive before the ground freezes solid here and I have a chance to pound the support into the soil. I'll lay radials right on top of the grass for now and fix it up right in the spring.

I just worked HK3JJH/HK0B on 80m on the ugly loop - Columbia/San Andres. He said my signal was 59, but it was a DX 59; probably in reality a 45 or 35 since I had to repeat my callsign suffix a few times. Nevertheless, I was never able to raise a Carribean station before on the G5RV (except a VI, and I'm not sure that counts), and certainly not one so close to the equator.

Maybe its just good propagation, but I also just managed to work both Ireland and Poland on the worlds ugliest antenna. 5x7 reports, and I didn't have to repeat information a bunch of times, so I suspect they were legitimate signal reports.

I guess we'll keep this up.

Steve,
I wasn't talking of feeding it with coax - I don't use coax except for VHF & UHF. On my wire antennas I use nothing but 450 ohm balanced feedline. But even when feeding it with coax you still get about 10% radiation efficiency on the second harmonic wheich means for a 100 watt signal you get 10 watts radiated. But why feed it with coax in the first place and be stuck on one band is my queston ? Coax is a fad that will never catch on ! [grin]

From: Steve Friis
Topic: 565 Message: 7040

Well, you have to include just coax fed when you talk of dipoles. And if you've read the original designer's goal, it was for an antenna that would work 20 meters primarily, and then as a bonus work as many other bands as possible.

The problem is, so many people who really don't have any concept of what is really happening with an antenna make snap comments bashing rather than make constructive comments. We've all done that at one time or another.

Back to the G5RV, and maybe to close out this thread for a while, it is an antenna that has been around for a while. It does work, when constructed correctly, for what it is intended to do. Is it perfect? For some, yes, because of the situation they find themselves in. For others, no, since they have other options available to them.

In two or three years, when the solar cycle 24 gets really going, it won't much matter, as the proverbial "bed spring" will work as an antenna, and you'll be able to work DX using it for a radiator. When some bands, like 10,12 or 15 really open, you can work around the world with 1 or 2 watts. So, during those conditions, you find yourself with an antenna that radiates only 10% of the power, and heats up the coax with the other 90%, but you get a 599 report, then who cares? When I look at the DXCC roll, I don't see where someone used 1000 watts but his antenna was only 5% efficient, or that the next guy used 50 watts from an antique radio with an antenna that was 100% efficient. It might be a bragging point for the guy running the 50 watts, but both managed to get their contacts.

I am one of the fortunate ones that has 2 acres to build antenna on. Actually I have a pretty decent antenna at home. But, when I travel, I use the G5RV. For me, it is the perfect antenna for what I want to do.

Steve/WM5Z
Just because you say I'm paranoid doesn't mean they aren't watching us.

From: al_kozakiewicz
Topic: 6985 Message: 7041

It couldn't be much simpler. I'll tell you what I did - just remember that in my case speed of construction was more important than quality of construction ;^)

I measured out 265' of #14 insulated wire - one wavelength at the lowest frequency of operation. I was shooting for 3.8 mHz. The basic formula is 1005/freq in mHz. You're supposed to subtract 5% for insulated wire - I did not. There is a calculator online somewhere for loop antennas that will also display the theoretical impedance and some other parameters.

I then slipped 5 1.5" PVC tee connectors over the wire (one for each support rope, less the feedpoint). I drilled holes through the connectors to attach the support ropes.

At the feedpoint of the loop, I used another tee that I had drilled 3 holes in - one for the support rope and two for the ends of the wire. To the ends of the wire I soldered my feedline coax and tie wrapped that to the support rope for strain relief. I then hoisted the whole contraption up into the trees with the support ropes.

This is really meant to be temporary until the spring, at which time (if I want to keep it) I will rent a bucket lift and do a better job of getting the supports higher in the air and as level as possible.

If I could have gotten my G5RV up 60' in the first place, I probably wouldn't have gone through this exercise.

I was able to get my WAS this weekend. I've been a ham for 32 years, worked every state a number of times, but with my career moving me every 3 years, I FINALLY got my WAS from northern Michigan. The contest helped me secure Hawaii!!! I probably had every state since 1980, but moved to go to college. Then one move after another until now. The certificate is on the way.

I am ONE state from a CW W.A.S., and that is Montana.

And all of this with a "limited space" vertical that outperforms my G5RV any day! :)

Variation:

If it survived the last ice storm, it wasn't big enough...

To those of us who work "weak signal" VHF and UHF this is all too
true, especially when working EME.

Some of us never have this ice/snow problem. Of course Micro bursts are
a completely different problem with the same result. ;)

Topic: 565 Message: 7045

Well, including coax feed depends on the antenna being a single band dipole or a multiband dipole. And the fact that he wanted a multiband antenna is my point - why use coax and be stuck on one band when all it takes is the same size dipole fed with ladderline and a tuner to get several or all bands ? I too have tried the G5RV and was not really satisfied with it because I like the low bands better - 40, 80, & 160 meters and even though I could load it up on 160, folks could barely hear me. I then switched to a 135' dipole fed with ladderline and got a very slight improvement on 160, and a great improvement on 80 & 40. But when I switched to the 40 meter extended double zepp, folks asked me if I bought an amplifier ! My very first antenna was a resonant coax fed dipole for 80 meters and it worked great on 80, but I hate being stuck on one band when my radio has so many bands ! So I switched to ladderline feed for my dipole and never looked back. And I never have to worry about a high swr either, and if I can hear them, I can work them !

Steve,
well said. I have to agree with you that propagation is the factor few hams are willing to consider, maybe because it cannot be purchased in local ham outfit!
I do not think it is fair that most G5RV discussions end up in comparing "on the air results" with dipoles. It seem that propagation and directivity of specific antenna setup are always missing in these very subjective comparisons.

But IMHO the main point almost everybody misses is that the antenna was designed for 20 meters and the "feed" ladder line is an active element of the whole setup.

Well, you have to include just coax fed when you talk of dipoles. And if you've read the original designer's goal, it was for an antenna that would work 20 meters primarily, and then as a bonus work as many other bands as possible.

The problem is, so many people who really don't have any concept of what is really happening with an antenna make snap comments bashing rather than make constructive comments. We've all done that at one time or another.

Back to the G5RV, and maybe to close out this thread for a while, it is an antenna that has been around for a while. It does work, when constructed correctly, for what it is intended to do. Is it perfect? For some, yes, because of the situation they find themselves in. For others, no, since they have other options available to them.

In two or three years, when the solar cycle 24 gets really going, it won't much matter, as the proverbial "bed spring" will work as an antenna, and you'll be able to work DX using it for a radiator. When some bands, like 10,12 or 15 really open, you can work around the world with 1 or 2 watts. So, during those conditions, you find yourself with an antenna that radiates only 10% of the power, and heats up the coax with the other 90%, but you get a 599 report, then who cares? When I look at the DXCC roll, I don't see where someone used 1000 watts but his antenna was only 5% efficient, or that the next guy used 50 watts from an antique radio with an antenna that was 100% efficient. It might be a bragging point for the guy running the 50 watts, but both managed to get their contacts.

I am one of the fortunate ones that has 2 acres to build antenna on. Actually I have a pretty decent antenna at home. But, when I travel, I use the G5RV. For me, it is the perfect antenna for what I want to do.

I don't understand why folks are seeing such high SWRs on their G5RVs.
My MFJ-969 always indicates a 1:1 before I go on the air.

Less than an hour ago I conducted a FB 20-minute QSO with 5 watts on
20m and received a 569 from Erie PA...in spite of ear splitting QRN.

What is the program you are using to control the computer? Is that Ham Radio Deluxe? What are the dimensions of the slinky loop and the size of the pot?

Would you really want to trap your mother -in- law? They can get pretty
mean.

I think it takes a bigger resistor and maybe some extra capacitance to
null out a brother-in-law.

7057. HF longwire antenna

Yahoo group: ham-antennas (2008)
Date: 2008-12-02 18:26:17 UTC
From: Doug Chlan
Topic: 7057 Message: 7057

Hi Group,

I want to make a HF longwire (random wire) end fed antenna for 80m & 40m. Can I make a full wave 40m antenna that can be used on 80m with the aid of an antenna tuner? Any help appreciated.

Cheers!
Doug...

The right way to do it, is to make the antenna long enough for the lowest planned band of operation.

An end fed should be at least 1/4w on 80m for 80m to work o.k., assuming an adequate RF ground to feed against.

My first 75m antenna was an end-fed wire around 70' long, far from ideal, it made contacts and loaded up o.k. with my manual tuner. As I added wire and moved to balanced antennas, the performance continues to increase.

If you can put up a ½ wavelength of wire for 80 meters (about 125 feet depending on what you want as a residence frequency (for instance 468 divided by the freq 3.75mhz for ½ wavelength, 234 divided by the freq for ¼ wavelength), and get it high enough in the air, you should have few problems as long as you use a manual tuner (some 'in radio' tuners probably won't handle it). I always keep an external manual tuner on hand for playing with antennas, once resonant, the internal radio tuner should work okay.

7060. 450 Ladder Line Standoffs

Yahoo group: ham-antennas (2008)
Date: 2008-12-02 20:19:09 UTC
From: kb3oyf
Topic: 7060 Message: 7060

Hi Group,

I'm putting up an antenna and want to use commercial 450 ohm ladder line.

What I'm looking for is standoffs to use with the wire (ie. from the mast, from the building). I've searched the internet and couldn't come up with anything.

Does anyone know where I could get standoffs, articles to make them, or any suggestions to make them.

Thanks for the help.

Joe - KB3OYF

One idea I saw a guy in Albuquerque use was to make dome using 1/2" PVC pipe and matching "T's". He cut 3" long peices of pipe, and glued them to the "T's". Then he drilled holes in each "T" in parellel with the pipe.

To mount the pipes to the wall, he used screws through the holes in the "T". He used wire ties to mount the feed line to the pipe section. In between each pipe, he twisted the feedline 1/2 turn.

He used this method all the way to the top of his push-up pole. Worked good for him.

Joe
I wouldn't worry too much about finding standoff insulators for that 450 ohm ladderline. The thing that I would be concernered with is the the interaction between the ladderline and the metal mast that will undoubtly occur each time you put RF on the feedline. It would probably be better to try to keep the ladderline as far away from the mast as you can(minimum of about 3 feet). This can be accomplished by bringing it away at an angle without any degradation to the signal or radiation pattern. If you don't consider this aspect you will probably have problems tuning the antenna on one or more bands. Just a thought.

Joe,

DX Engineering makes what they call "ladder line supports". They
might give you a starting point.

From: ad7gr
Topic: 7060 Message: 7065

Joe, The recommended spacing of ladder line away from metal is three times the spacing between the conductors of the ladder line. If you are using 2" ladder line then the offset would be 6".
A good read is "All About Ham Radio Ladderline" on www.athensarc.org/ladder.asp and I recall the ARRL having a article called "The Lure of Ladder Line" on their website.

Standoffs can be just about anything that is non-conductive. I have used electric fence standoffs, posts, egg insulators, etc.

73,
Ed - AD7GR

maybe you can set up a fullwave for 40 with a 1:9 stepup transformer and use it on 80 as an endfed halfwave .... on both situations the ipedance will be high (voltage fed) so it is worth a try

Subject: [ham-antennas] HF longwire antenna

Hi Group,

I want to make a HF longwire (random wire) end fed antenna for 80m & 40m. Can I make a full wave 40m antenna that can be used on 80m with the aid of an antenna tuner? Any help appreciated.

Cheers!
Doug...

I use ladder line and my shack is in the basement with metal siding on the house so I had to be creative I used 1/2 PVC for stand offs with 3" L brackets and small hose clamps to attache the PVC to the bracket you can use a larger hose clamp to attach to the mast but on the side of the house I just used the screws that came with the brackets to attact to the house. I dont have to worry about a mast the center support is a 38' wodden A frame.
Hope this helps

> I was able to get my WAS this weekend. I've been a ham for 32 years, worked every state a number of times, but with my career moving me every 3 years, I FINALLY got my WAS from northern Michigan. The contest helped me secure Hawaii!!! I probably had every state since 1980, but moved to go to college. Then one move after another until now. The certificate is on the way.
>
> I am ONE state from a CW W.A.S., and that is Montana.
>
> And all of this with a "limited space" vertical that outperforms my G5RV any day!

Congratulations on your WAS. I first achieved WAS in December 1989, after a little over 10 months on the air with 5 months as a Novice and 5 months as a General. Mine was a multiband(80,40,20,15,10) and multimode(CW and Phone) WAS. I was using a 10 meter dipole and a 60 foot U shaped wire fed at the corner with a single wire feed into a homebrew tuner. Both antennas were in the attic.

Right now I'm going after a PSK31 WAS using again two attic antennas, an AEA Isoloop and a 60 foot half wave open loop fed with twinlead into an MFJ balun and LDG Z11 Pro autotuner. Since June when I started, I have worked 37 states and confirmed 32, mostly on 20 meters, with some 40 and 30 as well.

It just goes to show even with compromise antennas, you can still do alot.

Good luck!

Hello all,
    If any of you have a "Tractor Supply Store" around they carry all of those insulators for electric fences and they work very well for all dipole work. I get a pkg of 15 end insulators for somewhere around 10.00 and also one's that can be used for center insulators very cheap. 73' from Elkton,Md

Thanks for the information on that. I forgot that places that carry electric fences would have material that would also serve as antenna insulators. After all the electric fence puts out a high enough voltage to burn plants aways and make you and cattle jump pretty good. I remember the cows standing in the creek, reaching under the fence to get something a little out of their reach. The fence would touch the back of their neck and they would bolt forward and break the fence.

7076. Re: [ham-antennas] Re: nulling with the indoor slinky loop

Yahoo group: ham-antennas (2008)
Date: 2008-12-03 17:23:41 UTC
From: Jim Coon
Topic: 7048 Message: 7076

We should probably leave the Gramma's out of it or you can really
increase the QRM as well as the QRN. Then you will need a much better
front to back ratio and may need to point the house in another direction.

7077. Re: HF longwire antenna

Yahoo group: ham-antennas (2008)
Date: 2008-12-03 23:35:32 UTC
From: k9qb
Topic: 7057 Message: 7077

I have access to cuttings of ABS and various other plastics...

I rip off little pieces about 1" by 3" on the band saw and drill
3/16" holes about 3/8" from each end...

If I'm in a pinch, I tie a loop of 6" with polyester rope(the really
cheap stuff!!) and hook my antenna wire up that way...

Anything to get an insulator...there's nothing magical about it!!
Geez...they're just insulators!

Be creative!...Mike, WA5PSE

wrote:
>
> Hello all,
> If any of you have a "Tractor Supply Store" around they carry
all of those insulators for electric fences and they work very well
for all dipole work. I get a pkg of 15 end insulators for somewhere
around 10.00 and also one's that can be used for center insulators
very cheap. 73' from Elkton,Md

7078. Re: [ham-antennas] Re: nulling with the indoor slinky loop

Yahoo group: ham-antennas (2008)
Date: 2008-12-04 03:22:55 UTC
From: Steve Friis
Topic: 7048 Message: 7078

Many Grannies fit inside the bandpass, so it is very hard to tune out.
But Grannies supress the harmonics, so here, they are welcome.

Steve/WM5Z
Just because you say I'm paranoid doesn't mean they aren't watching us.

7079. Re: [ham-antennas] Re: nulling with the indoor slinky loop

Yahoo group: ham-antennas (2008)
Date: 2008-12-04 20:13:40 UTC
From: Jim Coon
Topic: 7048 Message: 7079

Harmonic suppression is always appreciated.

Steve Friis wrote:

Sigi,

I don't quite understand your advice. Why do I need a stepup transformer? Won't the antenna tuner just take care of things?

Cheers!
Doug...

From: Siegfried Jackstien
Topic: 7057 Message: 7081

the stepup is to lower the swr on the coax .... so the losses are lower
if you feed a voltage fed antenna swr will be VERY high so additional loss is on the line
your tuner in the shack will tune the line but no output of the antenna cause it is a very high impedance on the feeding point
hope you understand it now

7083. Re: Long Coax Run - Having Trouble Making Contacts

Yahoo group: ham-antennas (2008)
Date: 2008-12-05 15:19:53 UTC
From: johnsobryan
Topic: 6923 Message: 7083

I put up a new antenna this week - the Par Electronics End Fed Dipole (EF-20) which I understand is a great antenna and I have achieved less than 1.5 SWR with no tuner. But to get this away from my house and metal roof, I had to run about 220 feet of coax. So it was a trade-off - to get the lower noise floor, I had to move the antenna and live with a long coax run.

But most of my contacts have been very weak (my reports 559 or so) and I have lost many since my signal was below the noise floor or faded. (Working 20 meters only).

With all the great reviews on the EF-20 antenna (and I agree it hears very well), I suspect that I am losing quite a bit of power through my coax, which is cable tv 75 ohm RG-6/U and I'm running 100 watts from my TS-930.

Before spending about $250 on really good coax, should I try anything else? Or spend money on an amplifier? My 930s puts out 130 watts, so even if I lost half the power in the coax, I would still be putting 65 watts to the antenna which should be enough to overcome the noise floor and be heard.

Thanks!

220 feet is a VERY long run for this thin cable....
with a better coax you have more output AND better receiving
you loose more or less half of the power i think ... depends of the cable you use
i don´t know what loss per feet your cable has but you said
it is 75 ohm cable tv .... swr is 1.5 cause your cable impedance
swr at the feedingpoint may be a lot higher
hope that helps a bit
ps: dont spend money for an amp before getting a better cable

7087. Rewinding Hustler RM-40 Mobile Antenna

Yahoo group: ham-antennas (2008)
Date: 2008-12-05 18:30:10 UTC
From: visualco2
Topic: 7087 Message: 7087

I have a Hustler Rm-40 Mobile Antenna that I think might be shorted,I can't get the SWR down at all. I'd like to rewind it for 40 Meters with 14-16 Ga. bare copper wire. Any ideas on the number of winds that would be required would be greatly appreciated.
"73" N1UVW

7088. Twinlead

Yahoo group: ham-antennas (2008)
Date: 2008-12-05 18:36:09 UTC
From: Andy
Topic: 7088 Message: 7088

There were some questions a while back about where to get 300 ohm twinlead, with sources drying up. If you have trouble finding any at your local hardware store ... I'm not recommending this one way or the other, just mentioning it.

MFJ @ 40-50 cents a foot.

MFJ's 450 ohm ladderline is a little cheaper than the 300 ohm twinlead.

Radio Shack was also mentioned. The last time I looked, my local Radio Shack had no regular twinlead anymore, all they had was shielded twinlead stuff. I don't know how that compares to "regular" twinlead (probably more lossy because no air dielectric), and I'm sure it wouldn't work well for things like those roll-up J-poles. We also hear things about quality problems with R-S coax and twinlead, so there's that to consider...

Andy

How many turns are on there now? Should be pretty close. You are only going up in size of wire, all other dimensions will remain the same? Only question is would the wire fit without shorting. Since you think the turns are shorted, that would mean that the insulation broke down under the heatshrink. I would be more inclined to think that one end or the other opened up. This is the usual case with Hustler coils. They vibrate and the shocks eventually break the solder.

I have never tried to open one to try to fix one, not that you couldn't try. Mine always broke on the stinger end. You can tell if it is indead open with an ohm meter from shaft end to stinger end. If it is open, then the ohm meter will read open. A grid dip meter would tell you where it is tuned, if there is some turn shorted.

Steve/WM5Z
Just because you say I'm paranoid doesn't mean they aren't watching us.

7090. I'd like your opinions

Yahoo group: ham-antennas (2008)
Date: 2008-12-05 19:59:03 UTC
From: Scott Laughlin
Topic: 7090 Message: 7090

In the spring of '09 I'm pondering an extended motorcycle trip from Texas to Oregon. I'd like to use my MFJ-9040 (CW) monobander in order to play radio along the way.

Last year I took along a pruned dipole, but all the extra cords, the necessary coax, and trees always in the wrong places sure took the shine off that idea.

This year I'll settle for the decreased gain of a MFJ 40m Hamstick. Even the smallest tuner is too bulky. However, I could live with the bulk of a MFJ-909 C-Matcher. Do you think it will provide a suitable match for a 5-watt signal?

I've included the website below.

http://www.mfjenterprises.com/Product.php?productid=MFJ-909

I thought the tuner needed some added inductance, but apparetnly this 909 does the match using capacitors only. Does someone have experience with fabricating a static, single capacitor that would do the job?

Many thanks,

Scott/n7net/qrp

From: Rick
Topic: 7090 Message: 7091

Scott,
The only thing tha the 909 does is that it transforms the low impedance of a mobile antenna to 50 ohms - its not really a tuner. In other words, you couldn't use it to match something like a random wire to the radio. But it should help you get a better match on your Hamstick antenna. By the way, you could do the same with a simple shunt matching coil which would cost a lot less !

From: Rick
Topic: 7057 Message: 7092

Yes you can, but make sure the tuner is at the feedpoint of the end fed wire to eliminate losses in the coax feedline. You will also want a good ground with this system.

Years ago I operated with an Atlas 210X on my Gold Wing. I used a Hustler setup, mounted to the crash bars with a trucker mirror mount meant for a CB antenna. It worked well, allowed me to contact hams all over North America on 20 meters. That setup had the other advantage of allowing different bands with very little extra hardware -- just another resonator for each band. It also gave me a nice SWR with no base matching at all -- meaning it has a good bit of loss, but still very usable. Unless you already have the Hamstick, you might consider the Hustler setup. Unless of course, you can get that old TRI-BAND Swantenna!!! HI...

Amen..... You will always get the most bang for your buck if spent on your antenna and that includes the feed line. This is the least expensive part of the station ,yet has the most influence of any componet. May I put it another way: You would have more success with a 50 year old transciever and a good antenna than with a state-of-the-art modern double throw down double whammy Dazzler 999 or any other bells and whistles rig and a noodle for an antenna. At 100 watts output you could be jepardizing your rig now . I hope I have danced around this subject in such a way as to get the point across , I just hate to beat around the bush. Chuck Wq5B

Earl,

Thanks for the suggestion. It certainly bears some thought.

I've riding a CB-900C the last five years. I'm sure I could find a place to mount it.

Yupers, bought it in Phoenix in 02 or 03. I've had two Goldwings, and I'd rather have a third, but they get pretty heavy in the parking lot traffic like Dallas.

I did some 20m from it the summer of 07 while camped at the Devil's Den in Arkansas. Other than than that it's been APRS with a J-Pole or a modified 5/8 that uses the motorcycle frame as a ground plane.

Yup, if 14 turns will fit with 14Ga. then that is what I would do. I had no idea they used something as small as 26Ga. When I had a set of Hustlers, I had the set rated at 1KW, not the 400W ones. No wonder the bandwidth was so broad, the coil has no 'Q'.

That's right, and the big ones are worse than the small ones, due in
large part to the metal end caps.

Good Morning!

When I first moved into the house, that was my first option - just to try, I put my hamstick on a tri-mag mount and mounted on the center of the metal roof up about 25 feet. It was very noisy (maybe from electronics, etc. in the house), plus on transmit, I couldn't get the SWR anywhere below 3 even with a tuner. For some reason, any antenna on or around the house is just very noisy, so the current location in the field is at least quiet on receive since it's away from the house; it's just the transmit problem that I have to solve.
Thanks.

If the noise is coming from the house, you might try to locate the source of the noise by turning things off and seeing there is an improvement in the noise level. If you can find the source, you can try to mitigate the problem at the source with things like ferrite beads and chokes on the cords coming out of the equipment. Look at the cord for the computer monitor and you will see a lump in it. That is ferrite choke used to keep the rf noise from the computer from going into the cord and being radiated.

It would be better to get the right coax for this run. I believe that rg213 would be a good one.

I put up a new antenna this week - the Par Electronics End Fed Dipole (EF-20) which I understand is a great antenna and I have achieved less than 1.5 SWR with no tuner. But to get this away from my house and metal roof, I had to run about 220 feet of coax. So it was a trade-off - to get the lower noise floor, I had to move the antenna and live with a long coax run.

But most of my contacts have been very weak (my reports 559 or so) and I have lost many since my signal was below the noise floor or faded. (Working 20 meters only).

With all the great reviews on the EF-20 antenna (and I agree it hears very well), I suspect that I am losing quite a bit of power through my coax, which is cable tv 75 ohm RG-6/U and I'm running 100 watts from my TS-930.

Before spending about $250 on really good coax, should I try anything else? Or spend money on an amplifier? My 930s puts out 130 watts, so even if I lost half the power in the coax, I would still be putting 65 watts to the antenna which should be enough to overcome the noise floor and be heard.

Thanks!

Have you tried simply putting a watt meter and a dummy load at the
far end to see what's coming out there? That's probably the absolute
first step in this scenario.

Yup. I did notice that. You can tell when a capacity hat has no effect.

Love my Screwdriver antenna. Works from 3.8-21.45 with no problems.
Handles all the power I would ever use mobile, and you can tell the Q is
high, on 75 meters, you have to tune every 10Khz or so.

Steve/WM5Z
Just because you say I'm paranoid doesn't mean they aren't watching us.

7109. Pre Amp

Yahoo group: ham-antennas (2008)
Date: 2008-12-06 16:27:43 UTC
From: Joe
Topic: 7109 Message: 7109

I know this is a little off subject of "Ham Antennas"
but i thought who would know better than these guys.

Ok, we all know all about the TV digital conversion coming shortly. Andn
I'm way out in the boonies of Southwest Wisconsin. Closest TV station
is 60+ miles away. over rough terrain.. Well rough for there in the
mid west, 400 foot hills,, and valleys. so in no possible way are the
stations quote un quote "Line Of Sight"

So it too BIG antennas, and BIG highest gain possible pre amps to get a
decent signal.

Ok after the conversion all the local stations will be UHF freqs now.

So I'm thinking of then taking down the giant VHF antenna,, it won't be
doing anything anyway,, except open doors to TVI for the pre amp true?

Ok this is a older pre amp coax output 75 Ohm coax

the inputs are seperate VHF UHF, and both are 300 Ohm twin lead.

Ok, whats everyone suggest to minimize TVI, cant afford to go out and
buy a just UHF amp, so was thinking of terminating the VHF input.

Thinking something as simple as a 300 ohm carbon resistor across the
terminals? Dead short may be a problem? don't know, I know they make
75 ohm loads, but this is 300, whats everyone think is the best to do
to make the best chance of reducing TVI?

I second that, especially when the maker of the antenna "advertises" using non-descriptive term "common coax" for feed line!
Little misleading to say at least.

It would be better to get the right coax for this run. I believe that rg213 would be a good one.

I put up a new antenna this week - the Par Electronics End Fed Dipole (EF-20) which I understand is a great antenna and I have achieved less than 1.5 SWR with no tuner. But to get this away from my house and metal roof, I had to run about 220 feet of coax. So it was a trade-off - to get the lower noise floor, I had to move the antenna and live with a long coax run.

But most of my contacts have been very weak (my reports 559 or so) and I have lost many since my signal was below the noise floor or faded. (Working 20 meters only).

With all the great reviews on the EF-20 antenna (and I agree it hears very well), I suspect that I am losing quite a bit of power through my coax, which is cable tv 75 ohm RG-6/U and I'm running 100 watts from my TS-930.

Before spending about $250 on really good coax, should I try anything else? Or spend money on an amplifier? My 930s puts out 130 watts, so even if I lost half the power in the coax, I would still be putting 65 watts to the antenna which should be enough to overcome the noise floor and be heard.

Thanks!

Steve,

Have you compared your screwdriver with your G5RV? I'm interested in knowing what you think.

From: Andy
Topic: 7109 Message: 7112

Just a quick observation or two...

> Ok after the conversion all the local stations will be UHF freqs now.

Are you sure your TV stations will be UHF after the conversion? Were they UHF originally? My understanding was that VHF TV stations, which are *temporarily* using UHF channels right now for their (experimental) DTV signals, will revert to their original VHF channels in February and permanently relinquishing their temporary UHF assignments. I thought the idea was to free up portions of the UHF spectrum for other use.

Anyway, my guess (and mind you it's not much more than a guess) is that a 300 ohm resistor should work OK for the VHF input, and a short is probably almost as good. A short would not be nice on an unused output, but this is an input, and it's not like it has any DC voltage across it. I think the chances are small of it going into an oscillation or something with the input shorted.

My suggestion: try a 300 ohm resistor with short leads, try a short, try an open, and see if it makes any difference. My guess: probably not much if any, as long as you don't go connecting wires (antennas) to those terminals.

Grounding both inputs to the preamp's case might improve (reduce) common-mode RF ingress. If concerned about the shorts, a pair of 150 ohm resistors might be used instead.

It's probably way overkill to use a 75 ohm F terminator with a 75:300 ohm balun, and anyway it would probably bring more RF into the preamp.

There's a few good RFI forums you could also try, including Contesting.com and QTH.net.

Andy

7114. Re: [ham-antennas] Re: Long Coax Run - Having Trouble Making Contacts

Yahoo group: ham-antennas (2008)
Date: 2008-12-06 20:27:27 UTC
From: Steve Friis
Topic: 6923 Message: 7114

Well, anyone using that antenna and expecting the same results as a full sized dipole is only fooling themselves. It is sort of like putting a rubber-duckie antenna on a walkie-talkie. It works, just not optimally.

So, saying using 1/2" coax over 1/4" isn't where I would be concentrating my efforts. I really believe you should look at moving the antenna back closer to the house, finding the noise source and fixing that.

As for your transmit signal, you are correct when you say that there isn't much difference from 130 watts to 60 watts. Even though my rig is capable of 100 watts, I rarely use more than 50 watts. When I need more power, I use the amp, which 50 watts drives it at 1200 watts. I could drive it with 100 watts, and get 1500, but I go for the cleaner/greener signal.

Steve/WM5Z
Just because you say I'm paranoid doesn't mean they aren't watching us.

No, I'd wager 90% or more will be moving.

Any that are on ch 7 or less will absolutely be gone to UHF, and 8 thru
13 most will also be moving, some may stay but not many . easily 90%
will be UHF,,

From: Steve Friis
Topic: 7087 Message: 7116

The G5RV doesn't trail well ;-) , so I use the Screwdriver antenna while traveling. While parked, we set up the G5RV, and it does quite well. I almost always check into the roadrunner net (3939Khz 0100Z) using the G5RV and people say I am as strong as when I am at home, which I have a Fan Dipole array at.

The Dipole Array is set up as follows;
Wire 1-----1.850 center/3900 center
Wire 2-----3.600 center/7.150 center
Wire 3-----5.320 center/10.115 center

Notice the double 80 meter tuned set. Gives me complete coverage from 3.5 through 4.0 Mhz.

My traps are all home made, and match within 2-3 Khz. I hand selected the door knob capacitors, and they are all NPO types rated at 7.5 KV and rated at 5 amps RF at 100 Mhz. Expensive, but should last a lifetime. The coils are 1/4" copper air conditioner water pipe. Nice high Q of better than 150.

My coax on both the home dipole array and the G5RV is LMR-400. The ladder line on the G5RV is the open window type rated at 450 ohms Z with #14 copperweld conductors.

For 20 and above, I use an AV620 vertical. Now there is a wet noodle antenna. One for criticizing. It is garbage. Someday I plan on adding another set of traps on each of the dipoles above for 10, 15 and 20. Might even ad 12 and 17 too. I plan on dumping the AV620. This, of coarse, if I live long enough.

Steve/WM5Z
Just because you say I'm paranoid doesn't mean they aren't watching us.

I wonder if this may differ by regions. I understood that there would be no more UHF and as yet no station has mentioned a move. All but one of the UHF stations are now btoadcasting in digital as well as analog. We had a compliance test run last Thursday by our Fox 4 and it ran on channel 4 . I suppose time will tell. Topic: 7109 Message: 7119

I'm resending this again because it doesn't seem to have made it out.
I think Yahoogroups is having problems again. Sorry if this is a duplicate.

Just a quick observation or two...

> Ok after the conversion all the local stations will be UHF freqs now.

Are you sure your TV stations will be UHF after the conversion? Were they UHF originally? My understanding was that VHF TV stations, which are *temporarily* using UHF channels right now for their (experimental) DTV signals, will revert to their original VHF channels in February and permanently relinquishing their temporary UHF assignments. I thought the idea was to free up portions of the UHF spectrum for other use.

Anyway, my guess (and mind you it's not much more than a guess) is that a 300 ohm resistor should work OK for the VHF input, and a short is probably almost as good. A short would not be nice on an unused output, but this is an input, and it's not like it has any DC voltage across it. I think the chances are small of it going into an oscillation or something with the input shorted.

My suggestion: try a 300 ohm resistor with short leads, try a short, try an open, and see if it makes any difference. My guess: probably not much if any, as long as you don't go connecting wires (antennas) to those terminals.

Grounding both inputs to the preamp's case might improve (reduce) common-mode RF ingress. If concerned about the shorts, a pair of 150 ohm resistors might be used instead.

It's probably way overkill to use a 75 ohm F terminator with a 75:300 ohm balun, and anyway it would probably bring more RF into the preamp.

There's a few good RFI forums you could also try, including Contesting.com and QTH.net.

Andy

I wouldn't use a carbon resistor. We used those to make white noise generators. Film resistor would be better for the extra couple of cents.

I dont think you are correct. The bbottom line is there is no need to
get a new antenna to receive the new digital channels. The old one
will work just fine

From: Chris
Topic: 7109 Message: 7123

The answer is yes, both VHF and UHF will be used.

Check here for your local allocations and plan.

http://www.fcc.gov/fcc-bin/audio/tvq.html is a search engine

http://www.fcc.gov/oet/dtv/start/dtv2-69all.txt is a plain text list

Lot of information on google about this, lot of misconceptions.

Until the transition, a lot of the DTV transmissions are on temporary
frequencies and also operating at vastly reduced power for testing.
After the transition date, they will increase to full broadcast power.

Joe, it looks like you are in between the Madison and LaCrosse TV markets. I think you are looking at the Madison stations. If my info is correct, all the stations in Madison EXCEPT the NBC are on or are moving to UHF. The NBC digital assignment is on channel 11, so you'll be needing the VHF side of the antenna for that one. I can research it more if you need, let me know. Most of the Madison TV stations come from a common candelabra tower on the west side of Madison.

Do you receive the analog stations OK now?

BTW, there are a few "low band", channel 2-6 assigned to digital channels across the country, for instance there is a channel 5 in the Toledo market.

7125. Re: [ham-antennas] Pre Amp

Yahoo group: ham-antennas (2008)
Date: 2008-12-07 19:47:11 UTC
From: Joe
Topic: 7109 Message: 7125

No thats not the whole reason for this message,

I do have awesome antennas for BOTH VHF and UHF, but being on the fringe, they are the highst gain posssible made commercial antennas, nOT RADIO SHACK STUFF, as well as with the pre amp. Granted it's Old school pre amp, and honestly i do not remember it's brand, but it was a commercial unit. not a consumer rig, Nice all steel/copper components etc. no plastic,, etc. and gain, on both bands were, 30 to 35 DB or somethng like that! With FM Traps, level converters where if One sig was huge compared to the rest so the amp wouldn't get swamped you could notch it back to share the load with the rest of the signals. kinda like sattellite work.. on the oscars, One huge sig steals all the power!, But this wasn't a problem anyway, out here there are no strong signals.

What I was thinking was since the VHF part of the amp is not going to be doing anything shortly, except leaving a door open for stray RF that is closer in freq to it's operating freqs to enter the system, I was thinking of simply more or less shutting that side of the amp down.. and looking fior ideas as to the best way to do so.

Why allow sigs that are close to the input freq even a chance to enter the system,
Thinking was I will have less chance of TVI if the lower active amplifying freq is above 470+ MHz than at 54 MHz.
Hey 5 watts on 2 meters causes TVI out here!

Out here sigs stink period, The antennas,,,

On VHF cut channel yagis, 6 elements on channel 3, Picture 6 ele monobander on 6 meters,, Not a lot of difference. It's a giant antenna, (and will be converted to 6 meter use when the change over happens) On uhf it's a 64 element collinear, again GIANT antenna. And everyone out here has learned height is NOT everything,, It is soo funny where you see antennas out here,, You have two games,

If you have one of the hills nearby that you own,, or can make arrangements with the landowner to share the signal you put up your own tower on top of the hill, and have your own mnini cable TV system, with pre amps on top, distributution amps along the run for your run will be thousands of feet.

of you do what we all call sweetptotting. And out here you see this more than any other type of installation.

You will see the seldom TV system of rohn 25 up past 250 feet holding TV antennas, Guyed with radio shack guy wire too! Or hey I just love the

80 foot tall rohn 6 with radio shack guy wires, no clamps just twisted wires.. Or the often seen 60 to 80 or even 100 foot rohn 20 or 25 that is totally self supoporting. NO GUYS!, and these things have been up for decades!

Anyway, most here go the sweetspot route, Just like you do with your HT on 2 meters in a marginal place you move slightly around and you'll find this one sweet spot the repeater is full scale.

People do this all the time out here with their TV antennas. It is soo funny, One neighbor you'll see the antenna 100 feet in the air on a tower,

And next door you'll see a 10 foot mast hoseclamped to a "T" post out in the side yard with the antenna 10 feet off the ground. And the guy with the antenna at 10 feet has a better signal!

If you happen to get even after a giant antenna and pre amp a 1000mv sig, youd be screaming praise to the RF gods out here.

So the main question here was, shortly the VHF side will be dead, and without having to spend hundreds if not thousands to replace that commercial amp with a UHF only version, I just was asking what everyones thoughts as to what would be the best route to take to minimize TVI.

since obviously we have little sigs to work with herem, and everyone is running High Gain, it takes little to kill the TV sig,

I remember when I first moved into this area, I lived in a small town of maybe 1000 people, fairly spread out,, the smallest lot ws like a full acre, but from my third floor apartment., Running a Drake TR-4 Barefoot, into a Johnson KW matchbox unto open line that fed a wire loop that excircled the roofline of the apartment building,. It got out pretty good, make thousands of contacts, and was a hidden antenna to boot. and glad for that,, for if they towns folk knew it was me their would be a re enactment of the Frankenstein monster movie with the village people coming with pitchforks.

If i was on,, no one watched TV,, I could at night, look out that beed room window with binoculars, and see homes on the other side of the valley, wrong side to boot I would be between them and the TV station so their antnnas and pre amps and qll were looking right at me.

These people were easily a mile away across the valley

Being a nasty teenager I laughed bout it,,

Tune up on 15 or 10 meters, and go " Hellloooo" and watch their TV's flash all the way over there. Yeah i know I was mean. And I was BIG into contestings then too, so some weekends no one watched TV for the whole weekend. It's that is how weak the sigs are. out here

I played,, On 15 meters one day, Tv set to ch 3.

with as little as 1/2 watt traces of herring bone show, 1 watt watchable but full herringbone. 5 watts, BLACK PICTURE TUBE! And I ran 200 watts from that old Drake! Then we had TVI filters Lowpass on the rigs and hugh pass on the antennas, toroids on all the power leads, every trick in the book it was just plain fundamental overload. period.

I'm more or less all by myself now, What neighbors I have a re vacation homes, so they eitherr do not watch TV or are on cable and or the birds, and no problems there. So i'm mainly concerned now with my own system. And thats where we stand. not onto the comment below about the existing antennas and the conversion,

If anyone belives the BS the government has been spitting out with this Better TV and all that, wait till Feb happens,, there will be congressmen asking for the heads of FCC officials or whoever pushed this through. Honestly.

I've been dealing with this already for at least 6 months out here. lI've set up at least 100+ cnversion setups, and less than 10% get away with the existing systems. And some can not at all, and had to resort going to Dish or direct TV, for they while now can watch their local channels, with the digital, nothing. the thing is,, out here people are accustomed to watching a semi snowy and or grainy picture. it's what they grew up with, it's the way it is, And are perfectly happy with it.

But this digital stuff any signal that is not perfect analog wise, forget it it will not decode it, and you get nothing! PERIOD! People out in this part of the world are PISSED!

If they made the change klike they did with B&W to Color, Fine no problem,, if there was a difference it was the tiny bit more snowy,, but this digital crap, if it would allow them to get a snowy digital,, theyd be happy, but the thing of perfect or nothing, 90% out here gets nothing!

And the links below are so out of date it's not even funny.

A fellow ham is the eengineer for CH 15 in madison and the numbers quoted on thisee pages are not even close, for channel assignment or transmitter power,,, especially power he know they are running at least 15 db higher power than what is on those pages and not even on the channel they say now.15 is already UHF analog 15 and they are moving to 19digital,, 19 an analog in lacrosse is going to 14 when it goes digital,, it's soo messed up,

here is Madisons summary,
3 to 50
15 to 19
21 to 20
27 to 26
57 to 32

L ACROOSE IS,
13 TO 39
31 TO 30
8 TO 41
25 TO 17
18 TO 15
19 TO 14

ANYONE SEE ANY LOGIC HERE,, NOT US.

Anyway after hundreds and hundreds installed, if you do not have perfevt UHF picutures NOW come feb you won't be seeing any at all.

And it's not going to get better,

Who cares about free TV? Apparently not the FCC.

Yesterday while the country was focused on the presidential election, the Federal Communications Commission voted to allow manufacturers to build portable wireless devices that will use television frequencies to operate. If you're one of the 70,000 viewers in southern Wisconsin that use an antenna to watch television, your free reception is in danger.

Companies like Microsoft and Google have been pushing the use of what have been called "white spaces" between TV channels to allow new wireless devices to operate. While this sounds good in theory, in tests they haven't worked out and often will fire up on a channel that an existing TV station uses for broadcasting. If you're watching that channel and your neighbor turns on his new wireless internet box, there's a chance your TV set will go to a blank screen with a "no signal" warning.

The FCC decided to not allow its usual public comment period on this proposal but rushed it through under cover of the election. Speaking for myself only (and not NBC15) I think this is a reckless abuse of power that was done with a predetermined outcome in mind and no thought of the unintended consequences. Not only will this badly affect TV reception, but will also affect wireless microphones in theaters, churches, schools and many other venues.

The Wisconsin Broadcasters Association sent out a press release today listing a number of organizations that have joined broadcasters in protest: state and local emergency management and AMBER Alert centers, labor unions, minority organizations, pro sports leagues, religious leaders and dozens of members of Congress among others. If free television is important to you, contact your congressional representatives and let them know that this was a bad decision.

(I'm Tom Weeden, advocate for free over-the-air television, and I approved this message.)

Here is a recent survey,,,
"Completely Unready Households"

We just received some information from the A.C. Nielsen audience measurement people today which estimates how many households haven't begun making the transition to digital television. It's not exactly current, but the picture it paints is a little troubling.

Nielsen attempted to measure how many viewers in the Madison market do not have cable or satellite, and have not either installed a digital converter box or bought a new digital TV.

372,990 - Total number of TV households in the Madison market
69,446 - Number of TV households which only use an antenna
19,092 - Number of antenna-only households which have at least one set converted to digital TV
50,354 - Number of antenna-only households still watching ONLY analog TV

As of May, fifty thousand southern Wisconsin homes (what Nielsen is calling "Completely Unready Households") still needed to take some action, and we now have less than 70 days until their reception goes away if they don't. Yikes.

some tests were ran with a few test cities, that were willing to shut off their analog sigs,

right now at least 15% of the population will loose their TV that they presently watch at no fault of their own.

Does the FCC care no,

they are lreaduy selling off the freqs even while rf is still spewing through them.

anyway wow this got way off subject.

Yeah Ch 15 is the only one that will be changing into VHF land so I guess i;'m stuck afterall,

There are two main towers,

And matter of fact, ch 15 and 57 are using the very same antenna, I said antenna not tower.. Thisng is this is how picky this digital crap isl. 57 rock solid, never a fade never a pix, never a lock up solid sig, yet 15 no sig at all, well maybe a frame or two every hour, (passing airplane?eteor burst?) anyway, according to tom the only difference is 15 is about 2 db less power. thats all.

2 db on a analog sig would hardly be even noticeable, but on this digital crap, it not there.

what a mistake. unless they got all the bugs out of it they should never force it on the public.

especially now, with thias economy,, like in the 30's radios, and movies took peoples minds off the economy troubles, come feb the people with the least chance of improving their signals are going to be the one hit the hardest with no entertainment. to escape into.

You know, I have to stir the pot. Why are the broadcasters required to make this change?

Seems to me, this really isn't in the best interest to the consumer, as far as poor people go. Middle class American's probably buy TV's fairly often, but the poor at the bottom of the economic scale are being penalized.

What about those people when we need to alert them, like for a tornado or hurricane warning, and we've taken away their TV?

Sure, I guess they can buy a convertor, but then again, why should they have to buy anything?

Someone explain to me please?

Steve/WM5Z
Just because you say I'm paranoid doesn't mean they aren't watching us.

Hi Steve,
The government auctioned off a lot of the frequency spectrum,back
in the mid nineties,that are used by analog tv.
However,each household is eligible for two $40 coupons,to be used
to buy converter boxes.I'll bet that there will be a lot of confusion
when the changeover takes place.DTV seems better quality,but I can't
say if it will be a hardship on some of the lower income folks.

7130. Re: [ham-antennas] Re: Pre Amp

Yahoo group: ham-antennas (2008)
Date: 2008-12-07 23:08:17 UTC
From: Joe
Topic: 7109 Message: 7130

I beg to differ on that,

from My installing activities I've been doing,, There are MANY people that have in here in Wisconsin TV's that are 40 50 years old, and work Fine. may are old retired farmers living on next to nothing, and without the help of some local donations these old married couples living out thwe last part of their lives, their only entertainment is TV, and in their situations I will tell you that come feb they will not have TV. and that's all they got left in their lives.

Yes it is sad,, I've even given away some stuff, but I'm flat out of help, and the dam has yet to burst.

There ya go,, come May, there will be a emergency bill in congress, that instead of a stimulus check everyone in the country will get garanteed digital Tv coverage. yeah there we go,,

These people 40 buck coupon on a 60 buck converter is as good as well as my dad said tiots on a bull. 20 bucks may not seem a lot but to a LOT of people in this country, 20 bucks can mean if they will eat or not.

thats why tyey are watching FREE TV ON A 1960's TV!!! cable, sattellite/ not an option free or nothing. and for sadly many in this country that is all they have.

Just like this imagine

By looking at what we know about how society and commerce would slow down, and how people respond, it's possible to envision what we might face. Unlike the 1930s, when food and clothing were far more expensive,as compared to today, today we spend much of our money on healthcare, child care, and education, and we'd see uncomfortable changes in those parts of our lives. The lines wouldn't be outside soup kitchens but at emergency rooms, and rather than itinerant farmers we could see waves of laid-off office workers leaving homes to foreclosure and heading for areas of the country where there's more work - or just a relative with a free room over the garage. Already hollowed-out manufacturing cities could be all but deserted, and suburban neighborhoods left checkerboarded, with abandoned houses next to overcrowded ones.

And above all, a depression circa 2009 might be a less visible and more isolating experience. With the invention of televisions and the proliferation of channels, it's getting easier and easier to kill time alone, and free time is one thing a 21st-century depression would create in abundance. Instead of dusty farm families, the icon of a modern-day depression might be something as subtle as the flickering glow of

millions of televisions glimpsed through living room windows, as the nation's unemployed sit at home filling their days with the cheapest form of distraction available.

Thing is,

In the 1930's a much larger part of the population was rural and agricultural. If a family didn't lose the farm to the bank they could grow their own food and make clothes. Today most of the country is urban or suburban and dependent on grocery stores.Amd mortages. and growing yiur own food, if yiou even knew how, the zoning laws woulndt let yiou do it anyway.. never mind have a cow or two or chickens in your yard.. I wouldn't be too sure about not seeing soup kitchen lines. Maybe a lot of those suburban lawns would become vegetable gardens, and backyards would have chicken coops.

Those abandoned suburban houses might have squatters, perhaps even their former owners. This is already happening now.

Regions like the Pacific Northwest which are already fast growing could be "areas of the country where there's more work" and be flooded with "laid off office workers." "Remember the Grapes Of Wrath"? Regions like the Southwest that are natural desert and have been overpopulated because of air conditioning could lose population if energy become unaffordable. Already scarce water could become a major factor in where people live.

A good deal will depend on the severity depth and length of the downturn, i.e a 2-3 year slowdown will differ from a 2-decade long depression

Back to basics -2010 style
-Cash is king; you're dead if you are in debt
-opportunity savvy buyer pick up assets at firesale prices ie pennies on the dollar
-frugality, cost cutting, semi illegal ways to save money (ie buy through your neighbor that is still working and gets a 40% employee discount. I
-rise in crime, theft, scams, counterfeiting, get rich quick schemes, This I see will be far greater than in the 30's. sadly back then evebnn one starving would never stink of stealing from a neighbor, but today?.....
-global trade collapses ie watch Baltic Dry Index (DBI), people turn to buying locally produced raw materials
-fringe lifestyle groups affering alternatives to poor ie dark greens,
-rise in fascist regimes,
-authoritarian parties offering control & back to the good times roadmap
-increased popularity of backyard depression gardens and possibly chicken coups,
-communal urban farms with cows, chickens and sheep
-High tech urban farming in skyscrappers
-regions with stable sustainable electrical power (hydro or nuclear)

fare better then ones dependent of oil or gas
-DIY industry grows, demand for affordable electric vehicles, DIY
projects ie people convert electric golf carts to makeshift on-road vehicles
-people who can afford it go "off grid selling solar power and
wind-power back to the utility
-growing vegetable and fruit "seed" sales
-books and classes on canning and preserving food,
-immigrants teaching locally born Canadians and Americans how to be
self-sufficient
-growing use of food banks and soup kitchens
-abandoned malls and schools become homeless shelters
-centralized preserving centers (attached to food banks) where neighbors
can bring in fresh produce to can and to share with the needy in
exchange for canning facilities
-doctors making house-calls
-The town strip mall will be replaced by the "swap ally" or roadways or
roadsides where people will gather daily for perpetual garage sales to
buy (whoever has cash) or barter trade for what you need. (Like
south-side New York city)
-On-line swap sites (like e-Bay) grow, but may become unaffordable do to
increased shipping costs
-Growth in the repo business, auction business and conspicuous
consumption recycling.
-Collapse of the supermarkets, malls and plaza's chain stores and
mega-box stores (due to the pending commercial mortgage bubble and lack
of sustained shopper traffic) and the return of the local mom and pop
corner variety store
-Increase in entrepreneurship, hobbies turn to businesses if your skill
is needed and popular
-Government becomes the major employer, offering work security but with
dropping wages
-death of the middle man, intermediary, distribution center, customers
go to the source if it exists locally
-return of the corner fix-it store
-unlicensed and unregulated neighbor-helping-neighbor daycare (children
swaps)
-growth of regional farmer's markets
-farm-to-mouth pilgrimages to rural areas and to farms to stock up on
produce and meat
-deflation favors renting over home ownership
-wild cards ie peak oil and oil shortages and resource wars (water and
other strategic materials, metals)

Hey Happy New Year!!!!

OK, I see what you are saying, the $40 coupon to buy an electronic gadget. In reality, what do these cost? I see that one electronics dealer has them for 89.95. It is a kit with a cable and who knows what else. So if they are $90 each and the government pays $40, who pays the rest?

Maybe I'm to concerned, but look at the demographics here. The mean income is well below the average here. Sure, I live good, my housing cost is low but most everything else is not cheaper. Food and fuel are right up there. So, the poor Mexican family working here, they just have to give up TV?

Just so you don't think I'm just a bleeding heart, I am very conservative. I do care about my neighbors, though.

Steve/WM5Z
Just because you say I'm paranoid doesn't mean they aren't watching us.

7133. Re: [ham-antennas] Re: Pre Amp

Yahoo group: ham-antennas (2008)
Date: 2008-12-07 23:28:55 UTC
From: Mike Check
Topic: 7109 Message: 7133

I ordered these coupons, even though I do not need a box. I was able to buy one box for tax only. There are $40 boxes, but it is hard to find them in stock here in San Antonio. Works pretty good on some rabbit ears up on the second story of my house. It IS all about $$$$ The government is selling spectrum.
This scares the crap out of me. Useful spectrum is currently finite. Will they next try to sell our frequencies when they no longer have spectrum to sell?

On Sun, Dec 7, 2008 at 5:21 PM, Steve Friis <wm5z@...> wrote:

The person that wants it.pats the rest. No Pay,, no watch period.
You Buy cable,, sattellite,, or converter box, or new digital TV, or
no Tv for you! Period,

You can't even steal your neighbors cable like in the old days, it's
digital!,,

>Maybe I'm to concerned, but look at the demographics here. The mean

>
>
More or less, again Buy The box,, buy a new TV,, buy cable or sattlite
service or no TV for you.

At least thats where i'm coming from. when the last great change of TV
was made it was mandated that all the older sets will also work with
it. when we switched from B&W to Color. It was federal mandate that
the new format of color signal can still be watched with no changes in
existing sets.

not this time. the government doesn't care, they want to sell off the
spectrum and make some mone7y.

Wow, sounds really bleak the way you wrote that.

I guess I should go out, buy a couple of cases of ammo to protect us
with, and set up the RV to live in.

Steve/WM5Z
Just because you say I'm paranoid doesn't mean they aren't watching us.

absolutely, then it's time for the amateurs to turn into CBers and just
break all the rules and laws and jam the new useres

Well Dave,

Some people just can't afford a new TV or cable or satellite receiver. These people are dirt poor! These are my friends and my neighbors. Some speak English, many can't. Some have good jobs, many have minimum wage jobs, and right now, a lot are without work. Most are really wanting to raise their families and live from day to day. Here we are, suddenly going to pull the rug out from under them, and then take away one of the few joys they have in life?

Well, and please don't take this to personal, but I don't think you can relate to how they feel Joe. You have to be a minority, beaten down all your life, have had so many things dangled just out of reach all your life, and now one thing you do have is going to be taken away?

It kind of makes me angry and sad. It also makes me worry and afraid. If you can't see why, then I feel sorry for you.

Steve/WM5Z
Just because you say I'm paranoid doesn't mean they aren't watching us.

From: Joe
Topic: 7109 Message: 7138

I agree with you fully,

no one asked the FCc to do this,, thery see a limited resource and like
opec are cutting back supply to raise prices.

7139. Re: [ham-antennas] Re: Long Coax Run - Having Trouble Making Contacts

Yahoo group: ham-antennas (2008)
Date: 2008-12-08 02:16:58 UTC
From: w4ddr@comcast.net
Topic: 6923 Message: 7139

You could perhaps go with two different antennas. Keep the one at a distance in the quiet location for receive-only, then put up another antenna close to the shack for transmit only. Some radios have a receive-only antenna port and will automatically switch between your receive and transmit antennas. If your radio doesn't have this, you (or maybe someone you know) could build a switch for this purpose.

Don't be discouraged by your experiment with the hamstick on the roof. There could be many reasons you didn't get a good match with that setup. There are many good options still left you could try. I'm sure you could find one that would work.

Concerning feedlines, my experience has been that the shorter the better, and you always want to get the lowest loss cable you can physically manage and afford. Nothing will ruin a perfectly good antenna like the wrong feedline.

Good luck!

Have you tried simply putting a watt meter and a dummy load at the
far end to see what's coming out there? I would consider that to be the
absolute
first step in this scenario.

Someone asked, or actually told them to do that.

Steve/WM5Z
Just because you say I'm paranoid doesn't mean they aren't watching us.

From: Steve Friis
Topic: 7109 Message: 7143

I don't know, who decided to do this?

Steve/WM5Z
Just because you say I'm paranoid doesn't mean they aren't watching us.

7144. 1/4 wave sloper question

Yahoo group: ham-antennas (2008)
Date: 2008-12-08 03:15:33 UTC
From: va1jgn
Topic: 7144 Message: 7144

Hi All

I have posted on here prevously in relation to the sloper and received some very helpful responses. Running some radials along the ground did help with tuning.

I am currently using the sloper with very low power 5-10 watts only. As I described in my previuos posts the sloper is attached to the side of the house. My concern is that the house has aluminum siding and the downlead droping from the sloper runs down along the side of the aluminum siding. There is only about a 1 foot seperation between the siding and downlead.

My question is would it be safe to turn up the power a bit more to say 40 watts for some PSK qso's. I am not sure with the 1 foot seperation if a fire hazzard to the house would be possiable. I would love to make a dx qso but do not want to smell smoke coming from the walls :)

Any comments on the possiable hazzards of turning up the power a bit would be appreciated. Thanks

Not much to do about antennas, but a beautiful shot of the moon, Jupiter and Venus along with the bridge lights.

We spend a long time in our yard admiring the sight in the sky. One neighbor wanted me to get out the eight inch newton reflector, but I was able to convince them that would spoil the view. (did promise to set up the scope some other time to peek at planets and a few of the objects in Orion.)

A couple of things here.The subscribers to cable and satellite services will not require a converter box,as I understand it.Some low power tv stations will not have to convert until 2011 also. This was started by the Clinton administration to generate revenue (and was likely pushed by the tv manufactoring industry as well). Motorola and many other companies were chomping at the bits to get the frequencies as well.This was in better times and I'm sure they thought the public would go for it more than they have.

Safety is paramount. Certainly.

But I had a similar setup once, and my coax was attached to the house. That was one of the best antennas I ever had.

OK, that is what I was wanting someone to pin down.

Now we have another bunch of them in the white house. Guess they will bo able to do more social damage.

OK, just so you don't think I was trying to set up anyone here, I was in broadcast, as an engineer for FM stations, and I guess it never occurred to me what was going on. I got out of broadcast about 12 years ago when I left the station I worked for in Albuquerque. I really feel blindsided as I am sure those friends and neighbors near by here felt also. I guess the only thing we can do now is live with it. But it sure is a bunch of crap dumped on the bottom rung of the social structure. These are the very people who want to govern the medical. No wonder they are trying so hard to nullify the 2nd Amendment.

Steve/WM5Z
Just because you say I'm paranoid doesn't mean they aren't watching us.

7149. RE: [ham-antennas] Pre Amp

Yahoo group: ham-antennas (2008)
Date: 2008-12-08 07:35:36 UTC
From: Callum M0MCX
Topic: 7109 Message: 7149

I can☐t understand your question. Are you only trying to minimise TVI..?

(Be aware that it's not just US amateurs that contribute here).

Callum McCormick
http://www.m0mcx.co.uk/

From: ham-antennas@yahoogroups.com [mailto:ham-antennas@yahoogroups.com] On Behalf Of Joe
Sent: 06 December 2008 16:28
To: ham-antennas@yahoogroups.com
Subject: [ham-antennas] Pre Amp

I know this is a little off subject of "Ham Antennas"
but i thought who would know better than these guys.

Ok, we all know all about the TV digital conversion coming shortly. Andn
I'm way out in the boonies of Southwest Wisconsin. Closest TV station
is 60+ miles away. over rough terrain.. Well rough for there in the
mid west, 400 foot hills,, and valleys. so in no possible way are the
stations quote un quote "Line Of Sight"

So it too BIG antennas, and BIG highest gain possible pre amps to get a
decent signal.

Ok after the conversion all the local stations will be UHF freqs now.

So I'm thinking of then taking down the giant VHF antenna,, it won't be
doing anything anyway,, except open doors to TVI for the pre amp true?

Ok this is a older pre amp coax output 75 Ohm coax

the inputs are seperate VHF UHF, and both are 300 Ohm twin lead.

Ok, whats everyone suggest to minimize TVI, cant afford to go out and
buy a just UHF amp, so was thinking of terminating the VHF input.

Thinking something as simple as a 300 ohm carbon resistor across the
terminals? Dead short may be a problem? don't know, I know they make
75 ohm loads, but this is 300, whats everyone think is the best to do
to make the best chance of reducing TVI?

Joe, a correction from my previous post - FOX WMSN Madison is moving from ch 47 analog to ch 11 digital. It's the only VHF in the Madison market.

There will be no problem with 1 foot separation. Here is a table for minimum approach distances for power equipment

http://www.highvoltageinfo.com/2008/04/alternating-current-minimum-approach.html

From: Chris Boone
Topic: 7153 Message: 7153

Sonmeone needs to get a life and learn the real story...HDTV is a result of Former FCC Chairman Reed Hundt (Rep)....
It was due to him ramrodding it through the FCC before he left is why we have it....lucky it was digital and not hybrid. It's happening, it works, it's real, so stop the bellyaching.....(and accept it)....Once DTV was a working thing, they realized they could say goodbye to the 700MHz band for DHS use, etc (and THAT was decided by a REP controlled FCC!)...
Hence channels 51-69 are gone soon.....(60-69 are gone as of 2/17/2009...the lower channels later on, even LPTVs).
Damn you people are so bassackwards...thought this was the ANTENNA list, not a political list (and a poorly informed one in that)...I came here for the ANTENNA talk....not to see all this political OT BS posted...Funny I don't see anything about the 2nd Amendment in all this.

7155. folding yagi plans for 2 meters?

Yahoo group: ham-antennas (2008)
Date: 2008-12-09 04:26:26 UTC
From: Skip Taylor
Topic: 7155 Message: 7155

Does anyone know of any plans for a fairly sturdy folding yagi for 2 meters? Basically it's for emergency use to hit a repeater about 60 miles away when needed.

Any ideas appreciated.

The antenna section of www.hamuniverse.com have some 2-meter yagis, though I am nt sure if any of them are foldable. If hitting a repeater is the priority they have some J-poles and other stowable antennas that might do the job.

Arrows antenna have one available where the boom is in three pieces. It is a 4-element yagi.

Thanks Jojo.

We've tried J-poles to get to the repeater. They just don't have the "oomph" needed that's why I thought of Yagi's. It's something we'll probably have to build as funds are limited (have to make 4 of them).

Regards,
Skip

Skip, can this be any yagi design - or must it be a folded type..?

I have some plans here that can upscale / downscale to 2m band.

Callum McCormick

Subject: [ham-antennas] folding yagi plans for 2 meters?

I needed a small beam to hit a distant ham in our club. I made one from a used TV antenna. Removed the UHF section , trimmed the remaining elements as required and a short piece of an element made a good gama match. That way the center of the coax just ran into the tube to form a capacitor. It is □foldable□ because they are shipped folded. You need to change the □X□ cross wires so it is no longer a log periodic style. Most are alum wire and easy to shorten and run to the nearby element thus making it a yagi style.

Rich , KDØZZ

Hi Skip,

The arrow antenna works well. Here is the link:
http://www.arrowantennas.com/

M2 makes some good antennas:
http://www.m2inc.com/index2.html

Also, have you considered building a small quad rather than a yagi?
Thunderbolt made a cubical quad for 2m that was easily set up in less
than 5 minutes but I think they have discontinued operations.

There are a number of plans around for portable quads and yagis. Here
is an example titled "A Portable Quad for 2 Meters":
http://www.arrl.org/tis/info/pdf/8009026.pdf

Good luck!

Hi Skip -

I have a page with photos and info about a 3 element portable beam I built at:

http://www.zievid.com/W6OT/RFI/Antenna.htm

This was built for 135mhz for RFI direction finding. It pairs with an HT set to the AM aircraft band and is used to track down noise sources. It can be taken apart and bundled for transport in a few minutes.

I think the original designs I based it on were for 2m, but they are all pretty easy to scale. The feed is very simple - just screws into the tubing elements, which are supported by a fiberglass rod.

It's not particularly light, but it works - one of our club members found a noisy pole across the street in a few minutes with it.

Hope this helps,

- Dave

I had focused on a folded type to try to limit space taken up. If there's a way it can be disassembled/reassembled easily then I think it could work as well.

20m and up in frequency it works o.k. I run an SGC 237 on a jeep Wrangler unlimited in this configuration. Below 20m it is a dummy load.

40m if I put a 36" mast section under the whip, I can make more contacts but have to tie the whip down if I am mobile at all.

Large coils are needed to be efficient 40m and below.

The tuner loads up down to 80m with the whip but if there is 1W ERP with 100W input, I would be surprised.

If you are serious about your mobile signal, a bug catcher or a full sized screwdriver and an amp are the right way albeit $$$$ to go.

Give http://www.k0bg.com a good long and careful read.

I would agree with Chris with the addition that hamsticks for 75 and 40 work much better than using the whip even when using the tuner to extend their bandwidth.

Topic: 7155 Message: 7170

Hi, Skip maybe this may help. I had a 2 meter yagi in the attic that I pick up at a ham fest. It's the Diamond A144s5r. This antenna you could take down in a minute. It has wing nuts to hold the elements in place. The only down fall is that it only handled 50 watts FM with a 9.1 dbi. It worked well. I replace it with a Elk 2m/440l5, It's a 5element log. You might want to look into the Elk antenna, it does a great job and it has 2 bands 200 watts with excellent gain.

Good luck and Happy DX

Does anyone know of any plans for a fairly sturdy folding yagi for 2 meters? Basically it's for emergency use to hit a repeater about 60 miles away when needed.

Any ideas appreciated.

Same here, I use a Icom AH4 with a 102" and it works good 20m and up. I have some extensions that I use a 3' extension and a 6' extension. Even with a all the extensions 40m is Good and 80m is fair.
 Good Luck

I would agree with Chris with the addition that hamsticks for 75 and 40
work much better than using the whip even when using the tuner to extend
their bandwidth.

I use a 102" whip cut to 78.5 inches for a base 2 meter antenna and have good reports on signal with FM.Some of my transmissions actually have to go up over the mountain ridge top besidehouse with no problem.
I do not use a tuner with it either.

I guess from the input, I should stay with the Hustler, mast and coil. I'd love to get a Screwdriver Ant. but $$ is out of the question right now. Thanks to all.

dear om
years ago i did a lot of contacts from my car with something like your setup
i had a yaesu fc1000 mobile tuner and a military whip on my car ....
it worked VERY well
when driving i had 2.5m on the mount and when i was standing on a parking place
i could ad some meters to have more gain on the lower bands ...
i liked it very much to resonate that whip with a simple pushing of a button on the tuner
i am sure that other models of mobile tuner will do the same
i took the military whip cause the lowest section of it can screwed in another to make
the antenna as long as you would like
sometimes i had 5.5m on my car while driving! ... bent in a quarter circle to the front..
the tip was about 3.9m from the ground and at the front end of the car
guying with two lines to the mirrors of the car
maybe your wife will be a bit upset but ... what do you want :-)
the tuer could tune the antenna with 2.5m on the topband (160) but with the longer antenna
the signals on the lower bands (160/80/40/30/20) where better
how long your setup has to be depends on the bands you want to use
and what tuner you will take for this ....
some tuner won´t tune a 2.5m whip on topband or on 80m
with some tuners you have to use a helical wound whip to be able to tune
on the lower bands.... see the manuals for the tuners before buying one....
if it says that a short whip will tune from 1.8 to 30 it is okay to buy the tuner
or you have to use the helical whip to mount it on your ballmount
on the last hamfest i saw such a whip for 60 euros brandnew ....
i asked to give me some info for this antenna ...
with most tuner you can use this whip from 1.8 - 30 megs so a real allbandantenna
the builder said that there where abt. 30m of whire on the whip so it will be easy to tune
with any mobile tuner ....
but with a straight steel or aluminium whip not all tuners will do the same job ....
maybe the cheapest way is to buy a used "firestick" cb whip (the very long one) and rewind
it with some more wire .... but you can try out to let it as it is and tune it with the
whip tuner
something to experiment with :-)
good luck

Have you consider getting the plate that allows 3 coils on your mast.
Then you won't have to change coils as often since you will have 3 bands.

I guess you didn't see my post about the MFJ unit? It screws together.
Dis-assembles and you can fit it in a tube or pipe for storage.

Hi Steve,

Yes, I saw that one. The only problem I'm seeing is the price. We are on a pretty limited budget so these will probably be units I have to build instead of purchasing pre-built commercial units.

Though that does look like a nice design MFJ has.

Thanks for the info,
Skip

OK, no problem. I didn't see it go by, so thought maybe it didn't make
the reflector for some reason.

An idea might be to go to your local hardware outlet and see if they
have aluminum box tubing. Then you could get some small copper tubing
for the elements, drill holes in the box tube to install them, and maybe
sheet metal screw for each element to hold it in place. Make a Gama
match for the feed line, and you'd be set. At our local Home Depot and
Lowes, they have 1" square box tubing in 3' lengths. I guess if you
really wanted to get fancy, you could fashion insulators out of PVC pipe
caps and just use a Balun to center feed the Driven Element. You can get
the dimensions from a Google search. There are quite a few designs
published there. Some are really excellent.

At our local Home Depot and
Lowes, they have 1" square box tubing in 3' lengths.

****

Dear Steve

this made me think about so old aluminum lounging chair where the straight sections are long enough (maybe they are not)
could then just cut out the longest pieces
people seem to be throwing these out these days and one should able to get at a recycling depot for say 5$ or may have one in the garage
the other way of making the boom is fully insulating material
here you need some kind of tube of square of good material
the pvc white may be a good compromise

anyways a few options

however I think Skip really wants some kind of quick foldup
4 element beam and direct connection would be nice at 50 ohms
do not forget some ferrite clip ons near the connection to the antenna over the coax

best
Paul in Guelph

I love brain storming.

I bet a piece of conduit pipe for the boom would work, and they sell those pipe clamps for fastening pipe to walls, kind of like an open P shape. These could hold the elements.

In the hardware section, I've seen thumb screws. You'd have to tap threads in the holes to make those work.

Make the Conduit pipe big enough for the elements to fit inside. Would make a really compact travel kit.

If the Driven elements were two pieces, snug fit inside a PVC section, then a coax could be attached directly. Should give a better than 2:1 SWR if tuned right. I'm guessing, but I bet the feed Z would be close to 35 Ohms.

Sounds like such a great idea, I just might go build one and take down my 2 meter loop to try it.

I have several plans floating in my head. Most involve PVC pipe with a combination of other materials.

I'll try to let all of you know what we finally create. It probably won't be till around end of this year or sometime in January.

Thanks again!
Skip

Yes Leonard I have, But the wind load on my 40m stick is enough to
bend the mast at high way speed. around town I suppose it would be OK.
I did Guy the mast ,I have pictures that I'll upload.

I saw a picture once that rather than using the plate that had all three coils sticking out at top like branches, they had made a curved bar that had them in line. If you looked at it from the front it looked like one coil but from the side they had 3 coils. This might work with your wind load issue.

I love brain storming.

I bet a piece of conduit pipe for the boom would work, and they sell those pipe clamps for fastening pipe to walls, kind of like an open P shape. These could hold the elements.

In the hardware section, I've seen thumb screws. You'd have to tap threads in the holes to make those work.

Make the Conduit pipe big enough for the elements to fit inside. Would make a really compact travel kit.

If the Driven elements were two pieces, snug fit inside a PVC section, then a coax could be attached directly. Should give a better than 2:1 SWR if tuned right. I'm guessing, but I bet the feed Z would be close to 35 Ohms.

Sounds like such a great idea, I just might go build one and take down my 2 meter loop to try it.

Steve/WM5Z
****

sounds pretty good to me, the conduit pipe is not too heavy either

I don't know how much is a Screwdriver Antenna but I found an
interesting whip antenna on Ebay. It's a Chameleon HF Multiband
Antenna for about 110$ or 120$ shipping included :

http://cgi.ebay.com/CHAMELEON-V1-HF-Multiband-Antenna_W0QQitemZ160303310062QQcmdZViewItemQ
QimsxZ20081207?IMSfp=TL0812071510002r23330

I got one of those and it really works! I use it as main antenna at
home on a mast. I just plug it in my AT-200PRO and bang, 10 minutes
later I was on the air.

Need more info. What type of base does your homemade antenna have? A simple commercial quarter wave isn't that expensive and is only about 20 inches tall.

The reason I asked was 3/8, nmo etc all have slightly different configurations for a mount. The most common I have seen for a suv besides mag mount is a hole drilled on the opposite front fender of the am antenna to keep the hieght down. Hope others on this list can help more.

7197. Butternut HF2V

Yahoo group: ham-antennas (2008)
Date: 2008-12-11 21:58:11 UTC
From: al_kozakiewicz
Topic: 7197 Message: 7197

Just to update on my antenna progress:

I purchased a Butternut HF2V and got it up before the ground froze solid here in NY. The radial kit was a ripoff - $100 for 12 pieces of precut insulated #14 wire. However, the rest of the antenna is the nuts.

I added an additional 16 radials by just laying some #14 wire on the ground and "stapling" it down with some pieces of coathanger. That will last until the spring when I'm sure my XYL will insist that I move the thing :-(I'll bury them then.

Tuning the antenna to resonance was tiresome without an antenna analyzer. I had to go inside; chart the SWR; figure out how far to move the resonance point; go back outside and adjust the coil length; repeat.

On 40m, the thing is reasonably resonant throughout the band. You get about 125-150kHz usable bandwidth on 80m without a tuner. I chose 3.795 as the centerpoint. I occasionally participate on a net at 3872 and the SWR is still tolerable there, as well as the upper part of the Extra class segment.

At any rate, I love the way this thing performs. I'm generally driving it with 500W and almost always get 59 signals reports from European QSO's that used to give me a 35 or 45 with the G5RV. It's not quite a pileup buster, but I usually get answered pretty quick if I can hear them.

Two thumbs up!

Al
AB2ZY

A quater wave ant will not perform well as it is small, only 19.25 inch.
you might want to consider at least a half wave mounted opposite the broadcast band ant.

7201. Re: HF longwire antenna

Yahoo group: ham-antennas (2008)
Date: 2008-12-12 04:24:16 UTC
From: ve7baq
Topic: 7057 Message: 7201

According to William Orr's 1972 Wire Antennas handbook, if you endfeed a 90 foot wire with a tuner you can use it with a fairly good antenna on 80 meters and 40 meters. One thing he stresses though is that you should have at least on ground radial for each band you wish to work. He recommends 62 feet and 32 feet respectively for those bands. I am using this arrangement right now and it seems to work out OK but I have to do a bit of pruning to get rid of RF feedback on forty meters. According to him the ground radial should be insulated wire and tape up the ends good to help prevent RF burns etc. VE7BAQ

There are actually times when a 1/4 wave can outperform higher gain antenna, and it's use should not be discounted.

Here in New Mexico, when traveling in the mountains and valleys and canyons, the higher radiation angle of the 1/4 wave will send a stronger signal up to mountaintop repeaters while 5/8 wave antenna were unable to access this same repeater from the same location. It also might work that way within the city.

Steve/WM5Z
Just because you say I'm paranoid doesn't mean they aren't watching us.

From: ad7gr
Topic: 7192 Message: 7203

The easiest antenna to homebrew for 2M is the 1/4 wave.

The choice of length, ie 1/4, 1/2, 5/8, etc is dependent upon your needs. The best performing antenna for flatland is not necessarily the best for metropolitan or mountain areas. In the city or mountains then the high angle pattern a 1/4 wave antenna has would be better. If in the country then perhaps the 5/8 antenna for its low angle concentration.

You should try meet your need. When I resided in Colorado it was good to have both and select the one for the needed pattern... just as you would if you were in your home HF station setup.

A simple mag mount is OK for the temporary or no holes mount, but if you can drill holes or use a trunk or hood lip bracket then by all means go that way. There are many good commercial mounts avail and you can make your own also... just be inventive. If you do not have any antenna books then I suggest you buy at least one. They are readily available from ARRL, CQ, WorldRadio, Etc magazines. The ARRL Antenna Book should also be available from your local library.

This is sort of related to antennas. Ground straps, I have a very smart friend who just happens to be a very smart electronics engineer who works on radio systems design for a very smart company. You see where I am going now. He said that braid ground should be avoided for grounding radios because it causes more noise than gets rid of. He said that the flat copper strips are the best. Now I have a heck of a lot of braid that I am going to use this weekend. I sort of never get around to grounding my gear. 5 years no ground to radios,just lucky here in California. Anyway what do you very smart people think about the braid causing problems or what is the best conductor for a ground to the gear from my brand new ground bus bar. Dang they are expensive!

7206. Re: [ham-antennas] Ground Straps

Yahoo group: ham-antennas (2008)
Date: 2008-12-13 02:27:09 UTC
From: Paul V Birke PEng
Topic: 7204 Message: 7206

Hesaid that the flat copper strips are the best.

Dear Rick

what about burying horizontal like a number of say 1m copper 1/2 pipes side by side

all joined of course

say a big "H" brazed solded up of standard Home Depot 1/2" tube and parts
with connect at centre of horizontal in the "H"

need to dig a trough for that a bit of digging

I am not sure just a vertical ARRL "water driven" in 1/2" copper tube is enough.

interesting about the braid, if he says that I would not bury braid

best
Paul in Guelph ON

I see no real reason not to use _*SHORT*_ braided ground wires to the ground buss. You are not going to be moving these around, but you might need to have some flex so that you can move the equipment, such as cleaning and dusting.

Yes the grounds will be short. The length is going to be around 4ft long. Running 7ft of 6AWG wire from the ground rod to the ground buss bar. From the buss bar I will then connect the radio's , tuners and the antenna switch. The switch was recommended since it has a shorting switch in it.
Jim, yes it will be mostly HF and VHF since they are on the bench and why not(now I say that).
Now off to work to make those ground straps.

Thanks and any other comments are always welcome

Flat copper strap has less inductance than braid.

Unles you operate only on one band, you will need multiple ground
straps from your "bus bar" to the ground stakes, one for each strap.

Remember - a 1/4 wavelength ground strap (or wire) may be grounded on
one end but definately not grounded on the other; by-pass it with a 1/2
wave strap.

I can imagine that copper braid might be a possible problem if the braid was moved around by expansion and contraction. There would be a lot of fine copper wires moving against each other possibly creating problems. I use copper braid (solder sucker braid from R.S.) to solder batteries together for my model airplanes and never noticed any problems, but when dealing with RF strange things happen.

The only problem that I can see would be the higher inductance of the braid over solid copper, but that wouldn't have much effect at HF unless the runs are very long

I have always told and been told that wide solid strap is better over braid because braid corrodes and loses it 'skin effect'.

As with wire, solid or stranded its surface area is much lower as compared to solid flat strap.

Look at the way big T.V. installation are. Granted some do use copper 'cable' but compair the size. Where copper strand is used, most of the time it is in the range of #00 or even 000. Never as small as #2 or #4.

IMHO

You are absolutely correct. Every broadcast installation I have attended used copper strap. It can lay on the floor and not become a trip hazard. Although I always ensured it was protected, much harder to do when the ground wire is like a 3/8" or larger pipe. It is actually easier to install than 00 or 000 wire.

For home use, you can get Andrews to sell you 2" wide. For a commercial station I always used 3" wide strap.

If the $ amount scares you, just figure out what a lightning strike would cost you, including the damage to the feed line, the radio equipment, the other accessories, and the building if it should catch fire. You want the ground strap to have much less inductance than the coax into the building. Using a copper strap will accomplish this.

I guess if you want to do it a little cheaper, one could get 1" copper pipe and flatten in out, but that seems like an awful lot of work. If I remember right, the copper strap cost us about $.50/foot. It is #22 GA.

Steve/WM5Z

said Steve

****

says Paul

I thought the "volume" of the copper parts made a better ground. So whether you flatten it or not would not make much difference. The ground should be some arrangement of connected copper bars and/or tubes to maximize a volume at a given depth in the ground. Should it not?
This would maximize the total area of a resulting "sphere" as the current enters from the operational surface area which would be more than the total area of all exposed copper surfaces making up the internals of "grounding volume".

or am I off base here?

Well, yes and no. Copper pipe would exhibit more inductance than the flat copper, although the cross sectional would be hard to beat. But the ground rod is different than the interconnect, which is where the flattening could help by lowering the inductance. Lower L reactance is wanted. You want to give lightning as low a resistance path as possible to the ground path.

Going into the ground with say 10' copper pipe is great if you can get them to penetrate. This is hard enough with plated steel ground rods! On a mountain top, where solid rock is on average 1/4" below the surface is a real problem, and broadcasters will either drill VERY EXPENSIVE holes to put ground pipes into, or lay a carpet of counterpoise to couple to the real ground, which can be several thousand feet down. Sandia Crest, by Albuquerque, New Mexico is a good example as real ground was calculated at 2,500 feet down in the winter, and 3,500 feet in the summer.

The counterpoise was built by the association of all the users on the mountain top, and it was a series of parallel copper cable 3/4" in diameter from the south end where the high power stations are clear to the north end where the FAA low power equipment and receivers are. I don't remember what the cost was, but even with over 200 users up there to divide the cost, it was still a pretty good chunk out of the budget.

At valley floor level, where the soil is sandy, like my home, putting 1" copper pipe into the ground was easy. I just put the garden hose on one end, turned on the water and let the water drill the hole. It took me less than an hour to sink 3ea. 10' copper pipes to almost 9'8", and then I just connected my tower legs to those with the copper strap. I also have a run of this through the windowsill to the station.

Steve/WM5Z

7223. Re: [ham-antennas] Re: Ground Straps

Yahoo group: ham-antennas (2008)
Date: 2008-12-14 02:46:10 UTC
From: Paul V Birke PEng
Topic: 7204 Message: 7223

very good Steve

I sort of forgot about the connection system to the "grounded copper mass"

A lot of technology in a good ground. Just learning this now.

thanks again

Paul in Guelph (ready to take my ham test here)

From: Steve Friis <wm5z@...>
To: ham-antennas@yahoogroups.com

Subject: Re: [ham-antennas] Re: Ground Straps

Well, yes and no. Copper pipe would exhibit more inductance than the flat copper, although the cross sectional would be hard to beat. But the ground rod is different than the interconnect, which is where the flattening could help by lowering the inductance. Lower L reactance is wanted. You want to give lightning as low a resistance path as possible to the ground path.

Going into the ground with say 10' copper pipe is great if you can get them to penetrate. This is hard enough with plated steel ground rods! On a mountain top, where solid rock is on average 1/4" below the surface is a real problem, and broadcasters will either drill VERY EXPENSIVE holes to put ground pipes into, or lay a carpet of counterpoise to couple to the real ground, which can be several thousand feet down. Sandia Crest, by Albuquerque, New Mexico is a good example as real ground was calculated at 2,500 feet down in the winter, and 3,500 feet in the summer.

The counterpoise was built by the association of all the users on the mountain top, and it was a series of parallel copper cable 3/4" in diameter from the south end where the high power stations are clear to the north end where the FAA low power equipment and receivers are. I don't remember what the cost was, but even with over 200 users up there to divide the cost, it was still a pretty good chunk out of the budget.

At valley floor level, where the soil is sandy, like my home, putting 1" copper pipe into the ground was easy. I just put the garden hose on one end, turned on the water and let the water drill the hole. It took me less than an hour to sink 3ea. 10' copper pipes to almost 9'8", and then I just connected my tower legs to those with the copper strap. I also have a run of this through the windowsill to the station.

Steve/WM5Z
Just because you say I'm paranoid doesn't mean they aren't watching us.

I guess if you want to do it a little cheaper, one could get 1" copper pipe and flatten in out, but that seems like an awful lot of work.

said Steve

****

says Paul

I thought the "volume" of the copper parts made a better ground. So whether you flatten it or not would not make much difference. The ground should be some arrangement of connected copper bars and/or tubes to maximize a volume at a given depth in the ground. Should it not?
This would maximize the total area of a resulting "sphere" as the current enters from the operational surface area which would be more than the total area of all exposed copper surfaces making up the internals of "grounding volume".

or am I off base here?

Paul in Guelph

What was the saying when our country was trying to get the other side to to agree to reducing nuclear arms?..."negotiate, but, VERIFY!!"

It's the same old saw I always get on...
Grounding is for transient voltage protection, period.

It's not for making an antenna work better or reducing received noise, for that matter!(although, under special conditions which a small fraction of one percent of hams enjoy, it truly can improve an antenna's performance!)

The noise coming into your radio is coming in through the antenna and not from your ground.

"VERIFY"...You can test this by buying copper strap at most major lumber yards...try hooking it up and also provide an alternate path using some #10 house wire (stranded or solid...it won't matter, trust me!)
Switch between them and see how much the noise changes...
It won't.

The NEC(Nat.Elec Code) describes "correct" grounding...
It is not intended to address the needs of the typical amateur radio station, but, if complied with, will afford protection that most of us don't presently enjoy.

Most hams,(yours truly included) are deficient in proper ground protection).

Interestingly, the NEC doesn't include the use of braided copper, but it does allow for the use of #6 stranded...but, that has nothing to do with noise reduction.

Again, the typical amateur radio station has needs that go beyond the NEC, but, the NEC is a good place to start!

Also, you can consult the many fine articles on the subject that the ARRL has published.

If you're wanting a magic bullet to reduce noice...best to look somewhere else...sorry!

7230. Push Pole grounds...

Yahoo group: ham-antennas (2008)
Date: 2008-12-14 15:47:39 UTC
From: Norm Blitch
Topic: 7230 Message: 7230

Nudging away from Ground Straps, but in MY mind related, please consider.

I have a 30' push-pole mast supporting a Davis Weather head. I have ADDED to this a MFJ Super-J for my local 6 and 2 meter needs (I have ALWAYS loved this antenna BTW). AFAIK, it is NOT insulated from the mounting U-bolt hardware (please correct me if I am wrong) , and therefore is connected electrically to the steel pipe. The FEEDLINE is connected to my Earth ground where it passes thru my window bulkhead. Given all this, should I ALSO connect the mast to my earth ground (copper pipe into the soil)??

Further, soon I will be erecting a 50' push pole that will be used ONLY as a hoist point for wire antennas. the ANTENNAS themselves will connect to Earth ground via feedline, but again, what about the mast itself??

I would do what ever I can to shunt lightning to ground. I also would put a two or more turn loop of coax between the panel and the pole. This will act as a choke to sort of force the lightning to take the path of least resistance to ground, and not into your dwelling. I use a 16" diameter coil with about 4 or 5 turns here. I have 3 verticals spread out across the property and a wire fan dipole array here, all doing this. All the poles have a ground rod, and the tower has 3 ground rods in an arc around the base. Plus we have a AV620 vertical. It, too has it's own ground rod. If it pokes skyward, it gets a ground rod. Period. With copper strap between the poles and the ground rod.

A push pole is a telescopic pole made of members of steel tubing where one section fits within the next section and so on. They are usually 10 foot sections, and come in lengths of 20 feet (2 sections) to 50 feet (5 sections). Sometimes they are called push-up poles, telescoping poles.

Hope that helps.

I saw some at Lowe's.

There's a few guys at hamfests selling what appears to be army surplus
that would be great for this. It's 3-4' sections of plastic tubing that
inserts into the next piece, like a really large vacuum extension. You
can get a plate for the foot of it as well as a ring for wire or guys.
Great for temporary too. Sometimes comes with what looks like an army
duffel bag to carry the pieces.

It's also the best way for a cheap acrophobic to get wire high in the air :)

The ones I have I bought at Radio Shack years ago. I don't know if they still sell them any more.

You could make your own, though. I have seen Aluminum tubing for sale at Texas Towers and other places. I'd start with their largest size, then progress down. I seem to recall they have 12' and 6' sections.

I have also seen steel tubing in similar sizes. The disadvantage of those would be rust. The Push Poles are zinc plated.

7238. Source for flexible rod for loop antenna?

Yahoo group: ham-antennas (2008)
Date: 2008-12-14 21:07:11 UTC
From: David Feldman
Topic: 7238 Message: 7238

I'm beginning to gather parts for a receive loop antenna project. The loop will be 1.5M/5' diameter and ideally I'd like to support it solely from the bottom. I'm looking for advice on suitable material for building the loop structure; I have in mind rod of the consistency of a fishing rod - where two pieces could be bent into semicircles, joined at the top under tension, and then lashed with wire that would make the antenna conductor.

Any suggestions, or does anyone know what this type of stuff would be called?

Thanks,

73 Dave WB0GAZ wb0gaz@...

Why for such a small diameter (1.5 meter) would you want to use wire?
The currents are very high, and to keep the efficiency high you would
need to use a very large diameter wire.

If you were to use copper pipe, it would be much easier to keep upright.

There are web sites devoted to Magnetic loop antenna.
<http://magneticloopantenna.com/>
<http://www.dxzone.com/catalog/Antennas/Magnetic_Loop/>
<http://home.paonline.com/dsarraf/Mag_Loops.htm>

to name a few.

GL. They do work, but there are a lot of pitfalls.

Yes,
I used one as a back up antenna, as time went I now used 2 of them as my main antennas,
made contacts through the entire globe
very satisfied with the Carolina Windom.
good luck
Have fun

For many years used the Fritzel on 80-10, mainly 80/40. Worked a treat at about 35' with the short leg sloping down to around 15' This was in the days before solid state so the Pi output tuned and loaded fine. With new rig, an ATU is advised

Sorry for the delay getting back to you. That auction is over, but I still have signs, so I have put a new auction up.
And yes, I will accept money orders. No personal checks though.

Thanks again. Here's the link.
http://shop. ebay.com/ merchant/ brjecass
Here is what the sign reads

"Caution

Beyond this point:
Radio Frequency fields at this site
may exceed FCC rules for human
exposure.

For your safety, obey all posted signs and
site guidelines for working in radio
frequency environments.

In accordance with Federal Communications Commission rules on radio
frequency emissions 47 CFR 1.1307(b)"

Texas Towers sells the push up poles up to 50 feet.
Rohn does make a 70 foot push up pole.

The aluminum tubing Texas Towers sells wouldn't be a good candidate
for a push up pole, to tight of tolerance.
You can only telescope it so far before it begins to gall and WONT
come apart, been there, done that.

The 50 foot poles only extend to 44 feet, if you need the full 50
feet you can extend the bottom by 6 feet by splitting a steel 8 foot
fence post down the center about 28 inches, put a bolt through it at
2 feet to keep the inner sections of pole from falling through.
Clamp the split fence post around the pole with SST hose clamps.
The steel fence rail brackets make good eve mounting brackets too.

put up a carolina windom and wish I'd found it years ago. Only up about 30 feet, and I now use it as my main antenna. Running a TS-430 barefoot and have worked over 100 countries and all state, and this is from the Aurora belt in Alaska! Chuck KL7OH Fairbanks

I bought a bunch of their aluminum pipes and after deburring worked just fine.

I didn't notice that they had the pushup poles. I used the aluminum because what was wanted was something to use with the RV. I wanted it to collapse into short sections, but still put my G5RV up at 38 feet or so. Works like a charm for us. stows under the storage compartment along with the other antenna parts, some tools and a few other items.

If it is as bad as the AV620, then I would say stay away. I have the 620, and it is a poor radiator. I hear better on my dipoles than I do on the vertical.

Hi,

No experience with that antenna but any antenna is better than none :) I have read about similar antennas and they do work. As you probably know anytime a tuner is used losses happen. If those losses are acceptable AND the antenna CAN'T fall on those power lines its a good compromise. Ventenna makes a portable dipole easy to set up take down. 200w max. Not cheap but might be an option.

dear greg
400 bucks for 43feet of tubing and a balun ..... that is hard
you have to use a tuner at the base of the antenna cause it is not resonant on any band
if you use a tuner in the shack the losses in the feedline will be very high
so for the external autotuner another 300 bucks .... not a cheap antennasystem
and any other antenna will be better i think
you can buy a 40 foot fishingpole for 100 bucks or so
ad some wire and buy a autotuner ....
or feed the antenna with ladderline and a tuner in the shack
would be not better but cheaper
for the rest of your money you can buy some other stuff

Please do not think that a antenna will give you a range of 2m to
160m. Two things will happen. The antenna will work fairly good
somewhere and you wont be able to get out of your back yard anywhere
else.

Antennas give and get.

Dear Greg,

I can't comment on the AV-6160, although Hy-Gain does have a good reputation. But, it is a lot of money for the hardware that you get.

I use a Hy-Gain AV-640 which is a resonant antenna on 40 through 6 meters. NO RADIALS !!! I have worked 299 countries with it. It works great. For a small house lot, it is worth every dollar spent. Any questions, email me. The price is about $400 but trust me, it is worth it.

Best Regards

Hy-Gain does make some good antennas but the 6160 won□t work good on all the bands, If you put a external tuner at the base you can make it load up on 2 or 6 or 160 but it will not give you a good radition pattern. They do make good multi band verticals. This is just a stick in the air. You can get very good vertical antennas with gain for 2 and 6 and a separate one with traps or stubs for 10 thru 40 or even 80. What band do you have to have??

From: Rick
Topic: 7248 Message: 7263

Well let me speak up now. Since I use a 40ft whip in the air that works fine for me I was looking at this, heck 3 more feet just might work a little better. My version works from 6m to 160m. If you look at other advertisements a few other antenna companies are trying to put out the same type of antenna. Antenna restrictions and condo living is pushing this. MFJ(who owns Hy-Gain I heard) has there own version and if you look carefully at their add it is the same picture. Like I said I am seriously looking at this version or the MFJ version(cheaper in cost). Also talking with a Hy Gain engineer who used the 30ft version(not released) he liked it and still uses it. Yes I know what else would he say. Anyway if you get it read the instructions a couple of times because from my experience I always miss the simple things.

7269. 160 Meter Dipole with 2 different wires?.

Yahoo group: ham-antennas (2008)
Date: 2008-12-17 12:15:55 UTC
From: visualco2
Topic: 7269 Message: 7269

I'd like to erect a 160 Mtr. Dipole or similar Ant.
I'm using RS speaker wire (14Ga.) "flat braided insulated" wire. The wire is 50'. Pulled apart I would have 100'. Which I know is not long enough. Would it be OK if I added another type of wire to this . I have a spool of 14 Ga. Tinned copper strand insulated wire appox. 100' so each leg of the dipole would be approximately 100'.
By joining 2 different wires would I be causing some weird distortions or currents?.
Thanks N1UVW

7270. Re: [ham-antennas] 160 Meter Dipole with 2 different wires?.

Yahoo group: ham-antennas (2008)
Date: 2008-12-17 13:14:50 UTC
From: Jim Coon
Topic: 7269 Message: 7270

It is a single wire. It won't make much difference. The things that will make a difference would be where you put it, how close to other objects isit?, how high off the ground is it? If you were connecting wire to tubing or pipe, it woud make more of a difference. The larger the diameter of the conductor, it appears the wider the band width of the antenna.

7271. Hi, I'm a 61 yr old new general

Yahoo group: ham-antennas (2008)
Date: 2008-12-17 14:37:06 UTC
From: greathounder
Topic: 7271 Message: 7271

I'm in the process of assembling my hf station. I've got a K'wood TS-2000 and yesterday I got my MFJ 998 auto tuner. I'm now waiting for the antenna. A 43ft MFJ 6 - 160 antenna. Here's where things get different. I plan to mount the antenna inside the garage, in the attic, and push the main part of it thru a 21/4 hole in the roof. Then I'll run my radials on the under side of the roof. With snow on the roof and a bad leg, I really don't think I should be climbing on the roof. What I'm wondering, should I get a choke unit or just put 10 wraps of coax around a piece of pvc pipe? Any how, that's the way I plan to do things. Anyone have any suggestions on a better way to do this. I don't have enough property to ground mount....Thanks...Bill N8VWI

Interesting plan, keep the group posted on how it works, sounds like a solution to a problem for a number of us. Almost a 'stealth' installation.

should make no problem
just ad that wire and it will be fine
the problem is on another side....
making the antenna from copper wire would result that the antenna will be longer and longer
after some time .... it will stretch out and after a few years you have to cut some inches
the resonance points will move lower and lower ... and in some days the antenna will break
i used aluminium fence wire for my antenna ...
very strong but lightweight
for some years it will work with your wire but you should know that this is not "forever"

Subject: [ham-antennas] 160 Meter Dipole with 2 different wires?.

I'd like to erect a 160 Mtr. Dipole or similar Ant.
I'm using RS speaker wire (14Ga.) "flat braided insulated" wire. The
wire is 50'. Pulled apart I would have 100'. Which I know is not long
enough. Would it be OK if I added another type of wire to this . I
have a spool of 14 Ga. Tinned copper strand insulated wire appox. 100'
so each leg of the dipole would be approximately 100'.
By joining 2 different wires would I be causing some weird
distortions or currents?.
Thanks N1UVW

dear bill
your vertical antenna with tuner under it should work well for dx
you have to put your tuner direct under the antenna (in the garage) ... not in the shack
the losses on the feedingline would be VERY high when the tuner is in the shack
if you have the tuner in the garage your vertical would work good on dx for the lower bands
for vthe higher band the antenna will put your power at a high angle so not very good
for receiving the vertical would receive much noise so it would be good to errect a dipole or loop
if you can do this.....
also for nvis transmissions a dipole or horizontal loop is better so better for short skip and local contacts ....
but a bad antenna is better than no antenna :-)
good luck and enjoy our hobby

Thanks to all for the reply's .
I'll keep that in mind, I never thought about stretching. Aluminum
fence wire sounds like a good choice. I'll check it out.
Thanks again and Happy Holidays to all

Hi Bill , glad to hear from a new ham. I do understand a bad leg , at 64 and after two back operations I have my legs give out on me at times and I can☐t climb a tower , or a roof in snow. About your roof what is it made of?? Don☐t know how the radials will work thru the roof. I had a 40M vertical in the center of my shed and worked OK. If you run guy wires, just take a square piece of polycarbonate and drill a hole in it slip fit with let☐s say 1in tubing and then a hole in each corner for the guys. It will hold its self in place at the hose clamp for the next section. I made my antenna from two sections of 1☐ conduit then a piece of 3/4 with an old CB whip as a top, made a 4 legged stand about 4 ft tall , the feet of the stand were just on the roof with caulk so I did not have to put a hole in the roof. It was supported by the 4 guywires and held up thru some rough winters and high winds. I try to keep form putting holes in my roof because leaks are not good for me. My shed roof is 40☐ x70☐, steel, but it did not provide a good of a counterpoise as a set of radial wires on 40 out to the corners of the shed. I moved the radio system to the house because I did not enjoy the trips thru the snow and made a tilt up system for my antennas.

You only need room for a 12☐ hole in the ground for a ground mount.

Rich , KDØZZ

There should be no problem with the two wires as long as you have a good solder joint. My only question is do you get ice and wind in your area. I do at my QTH , mid- Missouri. I have to use something stronger to keep it up. I used 14ga copperweld for the antenna and then small steel cable out to the supports. You will have a lot of stretch with soft copper for 160m.

Rich ,KDØZZ ,

from the middle of Missouri , out in the sticks with the hicks and the ticks.

Bill,

If this were me, I would continue with your installation as planned and use half a dozen good quality, large ferrite clamps. It☐s just my preference. I have used turns on PVC piping but I prefer the clamps. For ease of installation (and I just think they work better - but I'm not scientific about this, it's just gut feeling!!)

Some comments / questions:

- Are you planning on putting in ☐tuned☐ quarter-wave radials for any particular band, say 30 foot radials for 40m etc..?
- Assume you are feeding this with coax because the antenna already resonates roughly on each of the claimed bands, yes..?
- Assume that you could probably get away without the auto-tuner because the TS2000 would dial out minor mismatches?

Sounds fun though ☐ best of luck OM.

Subject: [ham-antennas] Hi, I'm a 61 yr old new general

I'm in the process of assembling my hf station. I've got a K'wood TS-2000 and yesterday I got my MFJ 998 auto tuner. I'm now waiting for the antenna. A 43ft MFJ 6 - 160 antenna. Here's where things get different. I plan to mount the antenna inside the garage, in the attic, and push the main part of it thru a 21/4 hole in the roof. Then I'll run my radials on the under side of the roof. With snow on the roof and a bad leg, I really don't think I should be climbing on the roof. What I'm wondering, should I get a choke unit or just put 10 wraps of coax around a piece of pvc pipe? Any how, that's the way I plan to do things. Anyone have any suggestions on a better way to do this. I don't have enough property to ground mount....Thanks...Bill N8VWI

Callum,

The problem with using ferrite chokes in this application (inherent mismatch and current flowing in the braid) is that they can heat up quite a bit. An air choke won't self-ignite.

As far as the rest goes, I've never quite understood the fascination with this antenna and others like it. I've read numerous glowing reviews, but ultimately you're paying $400 for 43' of aluminum tubing, an insulator and a few SS screws. Tubing stock with pre-cut slits is only about $1 a foot. This is almost 10x as much. I just don't get it.

With a resonant vertical mounted above the ground, you need resonant radials. What do you do with a 'multiband' non-resonant radiator? At least when you mount a vertical on the ground, you don't need to worry about the resonance of the radials, unless perhaps you're in a desert.

Just my thoughts,

Al

I understand if you have room you should put up a resonant dipole for each band you want to operate. The G5RV, OCD, etc with a tuner are all a compromise antennas. Am I correct it would be better to put a resonant dipole up for the band I want to use the most and then use a tuner for the rest? Thanks.

It depends on what band(s) are important to you and what you have the resources for. If, for example, you want to work dx, a resonant dipole mounted too low will greatly disappoint. A compromise antenna might actually work better.

7290. Tower installation questions

Yahoo group: ham-antennas (2008)
Date: 2008-12-17 19:49:31 UTC
From: wa7dxz@aol.com
Topic: 7290 Message: 7290

I would like to install a short tower on my property. I am not sure of the brand of the tower, but it is of the style of the Rohn 25.

I want to put it up about 32 feet tall. It will only support a dipole.

Here is the question. I cannot dig a hole 3 ft x 3 ft... due to water line problems. I can go 2x2, and 3 ft deep if I had to. BUT
I would like to first dig a hole 18 inches square, only One foot deep... then I would like to drive three metal pipes (3/4" black pipe, gas pipe), in the ground 4 feet, then slip the legs of the tower over these pipes, and run them up into the tower 2 feet. So the tower would be setting on these three pieces of pipe. Then bolt the tower legs to the pipes. Then, cover -fill that hole with concrete.
Then, bracket the tower ON TWO SIDES, to the house... at the one foot level and the ten foot level.
remember the tower is only going to be 32 feet tall... holding a dipole.

Will this be a sufficient installation> Ground here in Arizona is like concrete... it is
NOT the usual midwest soft dirt.. Those pipes wont move, and are not subject to frost heave.

I have done this before with NOT Problems...but I need to present a plan of some type to my building countyoffice, for them to approve a plan, before issueing a building permit. The tower will be sittin on three pieces of pipe 4 ft into the ground, bolted to those, a foot of concrete over that, and then brackected Twice to the house, at the 10 foot level. I will also bracket it at the two foot level, on two sides of the tower... thest braces will be at a 90 degree angle, the tower sits in a corner alcove.

I feel that this will be more than sufficient for this tower,,, but I have to convince the building inspector of this. My concern is only that the tower (base) is not in a yard of concrete. But I feel the pipes. along with the douple brackets, at two angles, one foot and ten feet from the ground, will be sufficient.
Is this going to convince them?

>>It depends on what band(s) are important to you

Hi Al,
40m, 20m and 17m. Dx and Local. Yes I want it all and I know physics only go so far. My thinking was 40m and 15m work well together and 17m is close by. 20m would be the band I would be willing to "give up". As for the hieght? Inverted V at 24 feet at the center or dipole at about 15 feet. I understand the closer to the ground the more NVIS it becomes for local work. I could try it and see but hoping for any advice. Hope that clarifies. Again Thanks.

Suggestion: Build or buy a trap dipole or fan dipole and put it up a inverted V. If buying look at Alpha Delta DX-CC or DX-EE. I think you will find the resonate dipole will work better than the G5RV for what you want.

Better to put up a resonant dipole for the lowest band that will fit in your property and tune it with a tuner and feed it with ladder or window line, rather than for your favorite band, which might not be the lowest in frequency. For me, that would be 160 for the lowest, but 17 for my favorite.

Have you given thought to using a FAN dipole array? What we've done here is to have an 80 meter dipole for the top, with 160 meters with traps on the top wire, then 40 meters with 75 meters for the next wire down, and 30/60 on the third wire. Works great, and doing it this way, on 80 meters it covers the whole band with SWR below 3:1 with 2.5:1 peak at 3750 Khz.

7296. Re: Room for one.

Yahoo group: ham-antennas (2008)
Date: 2008-12-17 21:20:39 UTC
From: al_kozakiewicz
Topic: 7288 Message: 7296

At about .3-.4 wavelengths above ground, a dipole is reasonably omnidirectional, with a takeoff angle of about 40 degrees. For 40 meters, that's about 50 feet up. Lower than .3 wavelengths and the takeoff angle will be literally 90 degrees.

For dx work, you want the takeoff angle low; less than 20 degrees, preferably lower. That's happens at around .75 wavelengths, or around 95 feet up on 40m.

The higher frequency bands would be proportionately lower; e.g. 20 meters would be half.

I can't get a wire antenna up much higher than 30 feet in my yard, so I opted for an 80/40 meter vertical to scratch my dx itch. It works very well. I have QSO's with Columbia, Russia, Latvia and Eastern Europe on 80m from my QTH in New York.

I'm also planning to build a compact (about 20' element length, 6' boom) 20m yagi based on plans from K4EAA. That should satisfy my dx itch further until there are real openings on 15m and 10m.

Regards,

Al

Yes. The issues with those though are supports for each wire in a narrow back yard. Being able to still walk back there is important :) and each wire would need to be spaced very close. The alpha delta dx-ee looks like a posibility building it or otherwise. Thanks again for all the suggestions.

That is possible if you feed it with ladder line. With coax trying a resonant antenna on other band will have a lot of loss. If you don☐t have a tuner then you can put up a ☐FAN☐ dipole and work several bands with one dipole. I have a friend , he has been at it since the 60☐s. Has many DXCC ☐s and other awards yet his antennas are a mess. He puts up a separate one for each band and runs RG-58 to the low bands and RG-8X on the uppers. I run Belden 9913 for less loss than RG-58 and a fan dipole. We both make contacts . What do you have up now??

If you do some searching you can find plans for a multiband trap dipole using coaxial traps. Might search for that one using "trap dipole coax"

>> . What do you have up now??

I use a Ventenna HFp verticle. (Put up take down) A good portable antenna that has gotten me across the country when setup near the ocean and just local near the house. Very high noise leval with high voltage lines within 100 yards. I've been thinking of getting the dipole option kit for a long while but wire is cheap and because a dipole is horizontal that should reduce the noise level. An inverted V is half and half as I understand it (at a 45 degree angle). I'm just looking for something more permanet. Oh and a little more serious about getting on the air more often.

Actually, if you want, the spacing of over 2' seems to minimize interaction. A while back someone said they built a 4 band fan dipole cut to 80/40 and got 30/15 as a bonus using zip cord. Now that is close spacing!

The 80m wire is 14ga copperweld , the rest are reg 14 ga copper. The copperweld is stripped from the center of some cable TV wire, I have a lot of snow and ice here, we had a storm last year that took down a lot of trees big tree , broke many cedars on my place but no problem with the antenna. The ends go to trees , the center is held up with a rope and pulley at the middle with a tilt up pole. You can see a picture of the tilt up in the picture section.

>>My fan is 80,40,20,17 and 10. Only one support wire

What gauge wire did you use to support the extra weight? Any problems with snow, icing up? Wind? Three supports total? Thanks.

I use a g5rv with a tunner and the only band I have trouble tunning is 160m. The rest I can pretty well tune in with my versatunner.

I understand if you have room you should put up a resonant dipole for each band you want to operate. The G5RV, OCD, etc with a tuner are all a compromise antennas. Am I correct it would be better to put a resonant dipole up for the band I want to use the most and then use a tuner for the rest? Thanks.

Nylon cord will work fine , I used the steel cable because the oak tree supports don□t do much good in the wind with nylon for me. You can use a weighted counter balance if the wind moves your trees lot. I put a small piece of polycarbonate (Lexan) between the antenna and the cable. Zip ties should not be a problem.

Thanks for the opinion guys.

With the antenna being so close to the aluminum siding and the coax entering through a small hole drilled through the siding I was just concerned with what the hazzards could be with running up to 35 Watt.

I plan on getting an inverted V up some and away from the house so this setup is only temporary.

Thanks

Bill,

Congrats on the General..I'm a 50yr old Advanced (since 1974 J)..and this is a great hobby! Got me several jobs and my career in telecom/broadcasting engineering..TS-2000 is a good all round choice...Some people don't like it (because of the wide coverage rcvr and some issues inherent in that), others LOVE it..I wish I could afford it but I couldn't so I bought a Yaesu FT857D ;)

As for the antenna, I am not a fan of MFJ..(they have the nickname Mighty Fine Junk)..some of their stuff is ok (previously made by other manufacturers) but a lot of their antennas are not worth the money.I CAN say Ive never dealt with the model you have.so I hope you have good luck with it.What you are proposing looks good to me.make since you are going elevated with the antenna, I would go with 4 radials as LONG as you can get them..preferably 130ft each but I doubt you'll be able to do that..IF you can do 4- 60ft each, you'll find the vertical will tune better on 80-10 than if you go with other lengths.HOWEVER, if you can throw up an inverted V 130ft long and feed it in the center with balanced line with the tuner, you'll likely have better results on 160-10..on 6, throw up a HORIZONTAL antenna like a PAR OA50 or someone's Halo or Square Halo...SSB on VHF is Horizontal..Vertical works on FM (also would work in a band opening on SSB but when the band is NOT open, horizontal is the way to go for most contacts)

The coax choke of 9turns of coax at the base of the vertical (properly done) will do you just fine.but for HF, I recommend an inverted V over a MFJ vertical.cheaper and works better..only needs one HIGH support and if you can run balanced line, SWR losses is less and you have a better time on HF.on 6m, use an antenna made for that band.you'll get better performance (Maybe work ya on 50.125 SSB sometime ;)

----------Original Message----------

I'm in the process of assembling my hf station. I've got a K'wood TS-

2000 and yesterday I got my MFJ 998 auto tuner. I'm now waiting for the

antenna. A 43ft MFJ 6 - 160 antenna. Here's where things get different.

I plan to mount the antenna inside the garage, in the attic, and push

the main part of it thru a 21/4 hole in the roof. Then I'll run my radials on the under side of the roof. With snow on the roof and a bad leg, I really don't think I should be climbing on the roof. What I'm wondering, should I get a choke unit or just put 10 wraps of coax around a piece of pvc pipe? Any how, that's the way I plan to do things. Anyone have any suggestions on a better way to do this. I don't have enough property to ground mount....Thanks...Bill N8VWI

If you do some searching you can find plans for a multiband trap dipole

using coaxial traps. Might search for that one using "trap dipole coax"

7312. Tuner MFJ 945E with G5RV Jr

Yahoo group: ham-antennas (2008)
Date: 2008-12-18 04:56:29 UTC
From: ki6lnx
Topic: 7312 Message: 7312

Hello everyone, I have a question.

I recently bought the above mentioned tuner as I want to get into the HF deal and I just want to know if when and after you are done tuning and getting the lowest SWR, do you leave it at tune mode or you set it to bypass? I read the instructions but pretty much they tell you what the knobs are for and not what do do with the button once lowest swr is achieved. I know this may be a little off topic what the heck why not. It Jogs peoples minds. I just want to make sure not to damage the equipment and it seems to tune anything so far. I am assuming that a lot of tuner have that bypass mode correct me If I am wrong.

Thanks a lot for any positive, productive input as it is greatly appreciated!

Bill,

If this were me, I would continue with your installation as planned and use half a dozen good quality, large ferrite clamps. It's just my preference. I have used turns on PVC piping but I prefer the clamps. For ease of installation (and I just think they work better - but I'm not scientific about this, it's just gut feeling!!)

Some comments / questions:

- Are you planning on putting in "tuned" quarter-wave radials for any particular band, say 30 foot radials for 40m etc..?
- Assume you are feeding this with coax because the antenna already resonates roughly on each of the claimed bands, yes..?
- Assume that you could probably get away without the auto-tuner because the TS2000 would dial out minor mismatches?

Sounds fun though - best of luck OM.

Once you tune the SWR for lowest settings just leave the tuner there until you change bands.

Leave it in the Tuner Mode. Otherwise there is no reason to have it connected. The Bypass mode bypasses the tuner just as though it were still sitting in your closet. The bypass mode is used if you have an antenna that already has a low SWR.

Putting it in bypass takes the tuner out of the circuit, like it isn't there. If it is bypassed it doesn't do any good to correct the swr. Tune it and leave it set to automatic so it can retune if the frequency changes or the wind takes down your dipole. (Just kidding on the last part)

You might be interested in my attic-mounted multiband dipoles - you can find the details at: http://www.qsl.net/g0kya/

Yes, you can spread them out like a spider. best way actually as you get minimal interaction.

I took the top off of mine and set the caps so all is right when you go from min cap to max which makes repeating the settings easier. In fact the only reason I am going to replace mine (not sell, it keep it for back up) is I want a higher powered auto tuner as I am going to get a 811H soon, to use for DXing. The G5RV and that tuner is a fine combination on 20.

7321. Re: Vertical Yagi for HF ?

Yahoo group: ham-antennas (2008)
Date: 2008-12-18 16:56:40 UTC
From: Paul
Topic: 6385 Message: 7321

This can be demonstrated fairly easily...

About 20 years ago I put up a modified "Moonraker 4"; it was modified to work on 10 Meters.

The antenna was put up so that the two yagis were at 45° to the horizon. This significantly reduced the interference from the supporting structure.

The feedlines were identical (electrical) lengths of RG-141. This ensures the phase shift in the two cables is ans will remain identical.

The feedlines wer connected to a switchable phasing network which allowed the following polarizations:

Horizontal

Vertical

Diagonal (45°)

Diagonal (135°)

Right-hand or clockwise circular

Left-hand or anti-clockwise circular

During periods of heavy QSB (E and F layer propagation) it was possible to watch the polarization of the signal rotate as much as 720 degees as it passed through the ionosphere.

The QSB could be eliminated by using either of the two circular polarizations.

Al,

I didn't know these ferrites heated up that much? You would need a fair amount of power for this to happen, yes? Being in the UK, we are restricted to 400w so I have limited knowledge of very high powers.

BTW, what's your definition of an "air choke" - the wound coax on a plumber pipe?

For info, I have build multi-band verticals but cheated by using an SG230 (and a high powered version) ATU / Coupler at the feedpoint and results were quite good, however I cut tuned elevated radials for each band. Random lengths and random radials seemed to be pretty inefficient.

Cheers!

I thought his antenna was resonant on each band? If it isn□t then he should
just use some aluminium pipe.

Bill,

If this were me, I would continue with your installation as planned and use
half a dozen good quality, large ferrite clamps. It's just my preference. I
have used turns on PVC piping but I prefer the clamps. For ease of
installation (and I just think they work better - but I'm not scientific
about this, it's just gut feeling!!)

Some comments / questions:

- Are you planning on putting in "tuned" quarter-wave radials for any
particular band, say 30 foot radials for 40m etc..?
- Assume you are feeding this with coax because the antenna already
resonates roughly on each of the claimed bands, yes..?
- Assume that you could probably get away without the auto-tuner because the
TS2000 would dial out minor mismatches?

Sounds fun though - best of luck OM.

Subject: [ham-antennas] Hi, I'm a 61 yr old new general

I'm in the process of assembling my hf station. I've got a K'wood TS-2000 and yesterday I got my MFJ 998 auto tuner. I'm now waiting for the antenna. A 43ft MFJ 6 - 160 antenna. Here's where things get different. I plan to mount the antenna inside the garage, in the attic, and push the main part of it thru a 21/4 hole in the roof. Then I'll run my radials on the under side of the roof. With snow on the roof and a bad leg, I really don't think I should be climbing on the roof. What I'm wondering, should I get a choke unit or just put 10 wraps of coax around a piece of pvc pipe? Any how, that's the way I plan to do things. Anyone have any suggestions on a better way to do this. I don't have enough property to ground mount....Thanks...Bill N8VWI

Finally someone else agrees with me. qsb is polarity related.

I had a similar arrangement, i has a Mosley TA-33 up 50 feet.

But i had it also on a U-110 rotor along it's boom. so i could go vert, horiz or anywhere inbetween,

And rarely ws max sig at when the elements were hoizontal.

even during a qso it would change

it was quite amazing to see that 20 db polarity null!

You've surely got to be joking ? Sure you leave it in the "tune
mode" or otherwise its not tuned. The bypass position is for when
you use resonant antennas and don't need the tuner.

It depends on how bad the mismatch is between the coax and the feed point. With "nearly resonant" antennas, say with a VSWR of 3:1 or less, I doubt it matters. When you're trying to match something further off, I wouldn't trust what might happen, especially at 1.5KW. A lot of people are tempted to make up for poor antenna with a good amplifier.

Air choke for me is 20 or so feet of coax wound on a 4" PVC pipe. You can also purchase them prefabricated. Some people just wind some coax into a loop and use tape to hold it together. I don't know if that works or not.

From: Frank MacKenzie-Lamb
Topic: 7331 Message: 7331

Hello All,

I am going to put two tube radios on the air, a Swan Cygnet and an HW-101. Hopwever, I don't want to uase a tuner AND I'd like to do CW with the HW-101 on 40 and SSB on 20.

can anyone make a good suggestion just how Im can do this?

Thanks

I could use some advise on antenna height and dual band dipole. This is my first antenna build. I have an Icom 718 with DSP with a Collins 30L-1 (with a buffer). I need to cut the antenna for the frequency because I don't have an antenna tuner. I have not use the rig yet.

1) I can put the antenna over the wood fence about 7', or I can put it in an inverted v having the top at about 20'. Will this make a diffrence and what type?

2) I would like to work 40m and 80m what type of balun should I use? Do I need a balun for each band? Have far apart do the two wire need to be from each other?

Thanks your time

Uhhh,

Put up an antenna?

Honestly,, hello? old tube rigs are far more forgiving about SWR than
ANY of this new stuff out there.

What do you think the plate and load do? they match the finals
impedance to the antenna feed line more or less a smaller range tuner
built in. And far more forgiving.

I ran on 80 meters a mis matched full sized 1/4 wave vert, 3 to one swr
for years on a old Drake TR-4 and had never a problem, 200+ watts out
every day. name me one of these new rigs that will do this without a tuner.

A guedeline was as all the old guys said,

If the Plate Dips, and the Load peaks without flattening out GO FOR IT!

Joe wb9sbd Since 1975.

here's one from left field: you can build a tuner if you like. I don't know how many watts that unit puts out but that's a variable you need to take into consideration. If it's low wattage, the project will be CHEAP. If it's higher wattage, you have to get bigger components but it's not that bad.

Many sites on the web go over building tuners. Google is your friend.

Best of luck.

Hi,

First let me suggest you invest in the ARRL Antenna Book. That will answer most questions on the basics of antennas. As for 7 feet off the ground that will be mostly NVIS style of an antenna. (Google it) To a point higher is better but any antenna is better than none. All antennas will handle some signals better than others. Build both and see what happens. Above all listen, listen and listen. You can learn a lot by tuning around the bands listening to the people who have been hams awhile.

Well since I asked about an antenna for 40 and 20 here goes what was suggested to me. Alpha delta dx-ee, fan dipole, two seperate dipoles, two seperate veticles, trap dipole, etc... Cut the antennas to resonance or somewhere close and run with them..

Having the antenna at 7' for 40/80M will result in a NVIS antenna. Will be good for local communication out to about 500 miles. The inverted-V with the apex at 20' will still have some NVIS tendencies but should provide some longer range stuff also. Both should provide a relatively omni directional pattern. Personally I would go the inverted-V unless I was doing it for a emergency communications setup.

7342. Re: Vertical Yagi for HF ?

Yahoo group: ham-antennas (2008)
Date: 2008-12-20 16:35:13 UTC
From: Paul
Topic: 6385 Message: 7342

Having this knowlege enabled me to make the SEVENTH 10 Meter QSO with Abania on the first day of operation...

Knowing that most of the other stations were horizontal and my antenna was vertical, I just waited until the Albanian station was almost pinning my S meter, and threw my call sign into the pile-up. He came back on the first call and told me that mine was the strongest signal he had heard so far that day.

I can just imagine the expression on his face when I told him I was running 15 Watts and I was MOBILE!!! The antenna was a 102" SS whip.

From: Joe
Topic: 6385 Message: 7343

It was amazing at times to see the difference. Like i said rarely was the signal the best at perfect horizontal. but don't get me wrong here either, it wasnt primarily any other polarity either. It was just usually stronger at some rotation other than horizontal,

BUT I also have to admit, not only does the polarity have a play in this, but he take off angle of the antenna also.

For my rotating the polarity are you also not adjusting the main lobe elevation take off angle also?

Horizontal being at a hugher take off angle than vertical?

7344. Re: Mosley TA-33M WARC

Yahoo group: ham-antennas (2008)
Date: 2008-12-20 17:28:21 UTC
From: phill104us
Topic: 7340 Message: 7344

Hi Joe:
I placed a picture of the antenna in the photo section in a folder named Mosely TA-33M WARC. Any help would be appreciated. I followed the assembly instruction as I understood they, but don't know if this antenna is designed with the two center elements higner on the boom than the director and reflector or if I did something wrong during assembly.

Thanks

That looks exactly as my regular TA-33 Looks except for an extra driven element. So you have it built right.

One additional thing, Moseley if I remember right just split the coax to each half,, and piossibly suggested a coiled coax choke thing.

I had much cleaner pattern and better swr by putting a 1 to 1 W2AU balun for a regular dipole at the feed points. In addition then it was much easier to waterproof the end of the coax also.

Thanks Joe: You have great recall. I added a second picture of the choke which came with the antenna, but I think I will take you advice and try a balun. Got to get it off the ground and do some testing. Its going on a 40ft. Rohn HDBX which I got free just for taking down.
Tnx Agn
Happy Holidays
73
Phil

Topic: 7340 Message: 7347

One additional trick,

If you run into a bad SWR setup,,,,,,

When I first put mine up, I thought there was something terribly wrong with it. I bought it used at a hamfest. And i thought that the traps were toast!

because it resonated nowhere in the ham bands, it was way out of the bands at resonance points. don't remember exactly where but it was like way high on 20 low on 15 and like above 30 meg on ten. way BAD!!!!!!!

I contacted Mosley about it, and the tech started laughing, I thought Yeah here we go time to buy new traps, he said try this,, no doubt you have a patch cable laying around right? I said uh yeah of course,, he said try adding a couple oof feet to the feed line. Now i said what? and I said this is good coax not radio shack stuff,, Iwas Belden,, the best they has in the early 80's. don't remember the exact modle,

anyway, I had a 2 foot cable added it to the line after the swr/power meter and not only was the SWR now good it was perfect! Like flatright where i hoped it would be.

I made a custom setting,, as you know there weere seperate holes for CW vs SSB setings, I do both all the time, so I set it 1/2 way between the points,, and that is excactly whwere it resonated too..

For a small 3 element beam it had an incredible pattern!

have fun I wish i still had mine.

I'm a little surprised at the question, coming from a extra class license holder...but since you're a jarhead I'll type slow for you (just kidding).

A monoband dipole cut to resonance is the easy answer, but I don't know what size or type antenna your location permits.

I've personally used an Alpha Delta DX-EE dipole in two locations that would likely work well on both 40M and 20M without a tuner if it was trimmed properly. I didn't trim mine...just put it up and used a tuner for touch-ups, but they were minor adjustments. I was using a Kenwood TS-520 w/ tube finals and they are pretty forgiving as long as you keep the SWR below 2:1. The HW-101 you refer to has a very similar final section as the 520 and should work fine; however, the larger the mismatch, the shorter your final tube life. There are currently a lot of 6146's around, but I'd get a spare set or two before the supply dries up.

I've also used a GAP Eagle vertical without a tuner and know several others who have used a GAP Titan without a tuner if your location favors a vertical over a dipole.

If you put up your cut to hand book length antenna as an "inverted V" a dipole comes pretty close to a 50 ohm match. Sometimes a balun is not needed to match the impedance, but a 1 to 1 for the match from coax to the wire.

You have a HW 101 I am green with envy and jealousy. The fellow K5LS who got me through my Novice/General had one. I do however have a HW-8 which I am restoring.

I agree with the other comments Tubes are a lot more forgiving and if I can give away my age a lot more fun!

Actually, an inverted vee at 20' probably isn't going to be noticably different than a dipole at 7'. And, to be kind, an 80m inverted vee with the apex at 20' and the ends at 7' is more like an 'inverted sag'! Until you get above 0.3 wavelengths in height, the takeoff angle is still 90 degrees. That's 42' at 40m and 84' on 80m. There's a difference in the beamwidth, but that's so wide at these heights that both are still effectively omnidirectional.

My experience says that if you want good performance on 80/40 meters and you can't get a wire antenna up at least 60', go with a ground mounted vertical. A low wire antenna will work better than no antenna at all, of course, but you'll be able to hear far more stations than you can work.

Use the formula for dipole 468/freq in Mhz.= feet. Add 5% more overall and put it up. Check for the lowest SWR and read the frequency. Then put the new frequency into the formula and you will get the new length. This process saves you from the cut'n try method.

You can zigzag the antenna wire to fit lot.

From: Peter Carr
Topic: 7356 Message: 7356

Hi to all and Happy Holidays.
I have a satellite array using two TV rotators. The horizontal unit is a U-100 on its side with the boom going through it. The azimuth unit is a Radio Shack which is less than two years old. The problem is that the Radio Shack freezes up. I've wrapped the unit in heavy plastic to keep the rain out and it still freezes up. The U-100 works fine. The best passes on AO-51 are early in the morning which is when the temperature gets down to 10 degrees. Later, when the air warms up everything is okay. Has anyone on the list a suggestion on how to keep the antennas turning?
Thanks & 73,

Hi Pete,
How about one of the heat tape strips,used to wrap along water pipes,to keep them from freezing.You are'nt supposed to wrap it over itself,but you should get about 4 or so turns around it,then tape it in place.Some of the better ones(a little more expensive)have thermostatic controls to set to begin warming at a certain temperature.They should be available at any hardware or home improvement store.They used to be about $20,for a six foot strip,but I have'nt bought one in several years.Hope this helps.

Topic: 7332 Message: 7369

Just my 2 cents, but I have always lived in an urban environment and tried several verticals over the years. My two favorites are the Butternut HF6V, which I used for almost 16 years (worked lots of DX and WAS), and my latest vert is a Gap Titan. Yesterday - even with these terrible band conditions - I worked a VE3 with 1 watt QRP using my Icom 718 and Titan vertical, and received a 569 sig report to boot, so I'd say the Titan is doing a pretty good job.

I'd vouch for either of those two antennas.

7370. Re: Can I ask this? ground mounted vertical

Yahoo group: ham-antennas (2008)
Date: 2008-12-22 18:44:09 UTC
From: al_kozakiewicz
Topic: 7332 Message: 7370

I'm using a Butternut HF2V for 80/40m and a compact homebrew yagi for 20m. I'm not operating on any other bands right now.

The Butternut vertical is about 32' high and I have 24 radials of the same length laying on top of the ground (I'll bury them in the spring after I'm sure we're past the XYL break-in period). It is a full quarter wave on 40m and is base loaded on 80m. I run about 500W of power and I regularly work the UK and the southeast US with no problems on 80m. Other recent 80m dx includes Poland, Russia, Spain, Canary Islands, Cuba, Venezuela, European Russia, Hungary, Bulgaria and Italy. My QTH is near Albany, New York.

I don't do a lot of local ragchewing, so I can't really comment on what, if anything, I've given up for the low takeoff angle. I have a horzontal loop antenna that's pretty low (20-30') that I occasionally use for receving because it has lower noise than the vertical that could be employed for NVIS, but I haven't needed to use it since I put up the vertical.

Pretty much if I can hear 'em, I can work 'em. Not always, but I'm a lot more satisfied than I was with the low mounted G5RV I used to have.

7371. Re: [ham-antennas] Re: Can I ask this? ground mounted vertical

Yahoo group: ham-antennas (2008)
Date: 2008-12-22 19:49:56 UTC
From: John Lewis
Topic: 7332 Message: 7371

Forgot to mention, just about any vertical you find these days are extremely overpriced for what you get - as a for instance, I paid $149 for my HF6V - they're now about $400 for the same antenna - in my opinion it's not worth it, but if you can find a good used one, that might be a deal.

Be sure and check if the vertical requires radials to operate properly (such as the HF6V) . If so do a web search for antenna radials to decide what to use -- there's lot of different theories on how many to use and how long to make them. The Gap doesn't require radials, that's why I switched. For the HF6V I buried 62 radials which were about 125 feet long (it was not fun) but eventually they kept working their way back up to the top of the yard where my lawn mower would destroy them, so I went to a no radial design. So far, no regrets.

If you possibly can, I'd just stick to one of the various dipole configurations (a whole heck of a lot cheaper and (50/50) just as good, sometimes better, but if you really need a vertical, the Titan or HF6V should serve you well depending on if you don't mind radials or not.

MJF makes a cheaper multi-band vertical, but I've never tried it...

7372. ground mounted vertical

Yahoo group: ham-antennas (2008)
Date: 2008-12-22 20:57:58 UTC
From: wa7dxz@aol.com
Topic: 7372 Message: 7372

I have a Hygain R7,,, no longer made, but i am very happy with it,,, uses counter poises, no need for ground radials. My best performance with it is mounted on a pole 8 feet high... much better performance than true ground mounting. Although these are no longer made, you can find used ones for $125... and I think they are well worth that. (I use mine on Navy MARS 80meters with a tuner)
But please be aware, if you put up a radial that requires radials... you MUST use the radials or you will have a wet noodle.
I had previously used a Butternut, I liked it a lot, and a GAP, which was also good, but, over priced.

Verticals work... only if you follow the instructions. Cutting corners won't work.

From: Peter Carr
Topic: 7356 Message: 7373

Hi Pat. That's a great idea. I'd used vacuum pump grease back in Physics Lab at college. It didn't occur to me that the silicone would work well at low temps. I'll give it a try. Thanks again for the info & Happy Holidays.
Best 73,
Pete Carr

i would try silicone based grease, not petroileum based grease. it is like vaseline. it does not thicken as the temperature drops. i have some but it is actually labeled "vacuum pump grease".
just a thought.

Hi Bob and thanks for the reply. A friend of mine has some "waterproof" grease. I thought all grease was waterproof! Anyway, there is access to the gear if I dismount the rotator so I'll have to take it down. We have had a string of bad storms here recently but the previous rotator lasted 8 years with the same antennas. I may have bought a defective one.
Again, thanks for the info and Happy Holidays.
73,
Pete Carr

Is there any way that you can take the rotor apart and use some type of grease on it to help or deter the freezing? Some type of grease on the bearings?
Or teeth, however it works?

7374. Keeping rotor unfrozen

Yahoo group: ham-antennas (2008)
Date: 2008-12-22 21:54:16 UTC
From: Frank MacKenzie-Lamb
Topic: 7374 Message: 7374

Also, I belive theier is a lithiumj grease that does freeze....check you local auto garage because they too carry grease that doesn't freeze. Putting a warm wrapper around a rotor IMHO really is unnessary unless that the only option open to you.

It is easier to open up the rotor and grease every moving part but remove all rust and make sure you don't have any gear teeth missing as it will throw your direction off.

Just my 2 cents and FYI for an OSCAR 13 user in the mid 90's.

Merry Christmas

It would help if you reveal your intentions. The tower is a good performer for strength and durability. I would not recommend it to anyone who likes to go up and work very often as it is a foot killer when climbing. It will support a mid -sized array without a hitch just be sure to add a standoff with a pulley and rope for wire antennas to keep you from having to go up/down often. Chuck Wq5B

7380. MFJ, what a pain in the ____!!!!

Yahoo group: ham-antennas (2008)
Date: 2008-12-23 02:41:25 UTC
From: greathounder
Topic: 7380 Message: 7380

A couple weeks ago I ordered that 43 ft antenna and a cable for my tuner and radio. The guy that took my order told me 2 things. 1 That I'd get a email when my order was shipped. 2 That my credit card wouldn't be charged till the order was being shipped. Well, I didn't get any email, that can happen, but I noticed that my card had been charged on the 17th. So Friday and today I waited for the UPS truck, and watched as it just kept going. So I called MFJ. The person I talked to, at first couldn't find my order. Then she found it and couldn't find the tracking number. But she did give me my order number.
After being on hold for about 15 minutes, she asks if she can call me back, cuz she has some checking to do. Later she calls me back to tell me it was just a big mistake, they thought they had my antenna, but they really didn't have it. It would probably be another week or two. When I asked about the cable, she said she never checked on that. What a way to run a company!!!
Oh, and later I went to their site, entered the order number that she had given me, it came up " no order found." Now if they sent me the order, and didn't charge me, that would be fantastic...Bill N8VWI

He he he,

yeah it all goes in swings,

I remember when I first got my ticket (1975) MFJ was either brand new
or not very old, and had all these little el-cheapo kits like they
bought 99% of the parts from Allkied Radio or something.

And it was a Big MFJ "Mighty Fine Junk"

I Myself never have had a problem with anything of theirs. The folk I
really hate for almost every order I have ever made has been taken and
charged immediately because when asked to make sure they have at least
one in stock, before charging,, oh yes we have it and it will go out
today this afternoon.

Only not to show up for weeks,,

AES In Milwaukee.

I at the time was less than a hour away..

7383. Re: [ham-antennas] Rohn HBX Tower

Yahoo group: ham-antennas (2008)
Date: 2008-12-23 04:20:54 UTC
From: Pat Turner
Topic: 7377 Message: 7383

thanks chuck. yes, i knew about the x brace when climbing. i have climbed towers since i was about 16 (i did lights in local AM and FM radio towers).. i have a old pair of boots that have a steel arch in them i use for climbing, and also have a custom made harness (from a previous employer).
just wondering if this tower could be made to tilt down. I have physical room to do this. i have a machine shop, and i am a structural, and can design and fabricate the hinges (pivots). any thoughts?
i also saw one BX tower that was mounted on insulators, i guess to be able to use the tower as a driven element. any thoughts.
it was just accidental that the tower is just two miles from where i am going later in the week (vacation), 300 miles away from me, so i am just taking a pickup truck.
i have an Alpha Delta DX-LB+ up at 18 feet now, in a flat dipole, so i will use the tower to
move the dipole up and make an inverted V.
Also looking at beams, not giant, as there seems to be some concern on other user sites that a large beam causes some tortional twisting of the BX type tower.
Not much info on the HBX, i have found the Shelby Company that supports the BX towers.
looks like i need a large chunk of concrete for the base, but i will do the structural calculations to see exactly what i need.
thanks all
Pat, K3PB

It would help if you reveal your intentions. The tower is a good performer for strength and durability. I would not recommend it to anyone who likes to go up and work very often as it is a foot killer when climbing. It will support a mid -sized array without a hitch just be sure to add a standoff with a pulley and rope for wire antennas to keep you from having to go up/down often.

i have an opportunity to get a Rohn HBX 48' self supporting tower. i realize this tower has been discontinued by Rohn. this tower is in really good shape, and is down on the ground in 8' pieces.
can you offer your thoughts, ideas, your experience, or other info about this tower.
thanks

Pat, K3PB

It's an EZNEC file. There's a free demo version of this program
included with the ARRL Antenna Book on the CD. You can get information
on this program and his for sale ones here:
http://www.eznec.com/eznec_arrl.htm

If you do try to run this file you'll have to raise it at least a half
inch above ground. EZNEC doesn't allow wires in contact with, or below,
ground, except for a vertical without radials.

73, Kevin

There is also a free demo version of EZNEC at one of the links at http://www.eznec.com . However, it isn't the same as the ARRL's special version that comes with the Antenna Book. Don't know if it matters in this case.

Andy

Yahoo group: ham-antennas (2008)
Date: 2008-12-24 17:29:35 UTC
From: Martin Hazel
Topic: 7395 Message: 7395

I managed to find a roll of four core cable in a skip its labelled as 75 ohm it seems to have decent shielding as well. What I was wondering and hoping you nice intelligent people could share with me is this. If I used this to run 4 antenna's and use a common ground would. Now I have a nagging feeling that this would be opening a whole can of worms. All of the cores are individually isolated, but its the shielding that is making me nervous.

What I was thinking about doing was using 1 cable to the entire mast rather than four, any thoughts

Martin

Hi Chuck, WQ5B and the Group,

I used to see a spiral loop antenna on the inside back
of almost every American 5 tube radio. Now that radios
are smaller and solid state, spiral loop antennas are rare.

A 3-D loop doodle is beyond my doodling capabilities,
but considering that I graduated from doodling with a pen
and paper to Windows Paint, I think I've made some progress.

To all those aspiring doodlers out there, my advice is to put your
line drawing of few colors in gif file format rather than jpeg file
format for better clarity.

Happy holidays.

A couple weeks ago I ordered that 43 ft antenna and a cable for my tuner and radio. The guy that took my order told me 2 things. 1 That I'd get a email when my order was shipped. 2 That my credit card wouldn't be charged till the order was being shipped. Well, I didn't get any email, that can happen, but I noticed that my card had been charged on the 17th. So Friday and today I waited for the UPS truck, and watched as it just kept going. So I called MFJ. The person I talked to, at first couldn't find my order. Then she found it and couldn't find the tracking number. But she did give me my order number.
After being on hold for about 15 minutes, she asks if she can call me back, cuz she has some checking to do. Later she calls me back to tell me it was just a big mistake, they thought they had my antenna, but they really didn't have it. It would probably be another week or two. When I asked about the cable, she said she never checked on that. What a way to run a company!!!
Oh, and later I went to their site, entered the order number that she had given me, it came up " no order found." Now if they sent me the order, and didn't charge me, that would be fantastic... Bill N8VWI

me it was just a big mistake, they thought they had my antenna, but
they really didn't have it. It would probably be another week or two.
When I asked about the cable, she said she never checked on that. What
a way to run a company!!!
Oh, and later I went to their site, entered the order number that she
had given me, it came up " no order found." Now if they sent me the
order, and didn't charge me, that would be fantastic... Bill N8VWI

Topic: 7402 Message: 7402

**** MERRY CHIRSTMAS ***
?
?HMY2K8 - A multiband HF transceiver (Homebrew):
?
for more information visit :
http://vu2sgw.blogspot.com/2008/11/hmy2k8-multiband-hf-transceiver.html
?
?
TECHNICAL SPECIFICATIONS :
Frequency coverage: Ham Bands
3.500 - 3.600 M.Hz (80 M)
7.000 - 7.100M.Hz (40 M)
14.000 ? 14.350 M.Hz (20 M)
21.000 - 21.350 M.Hz (15 M)
28.000 ? 28.350 M.Hz (10 M)

Receiver :
Single conversion receiver with 10.000 M.Hz Cohn filter.
Low noise figure, 2.2 K.Hz SSB band width, 1.5 W audio O/P.

Transmitter :
RF O/P - SSB - 90 W (DC PWR I/P)
CW - 60 W (DC PWR I/P)
Built in CW side tone, CW delay, pwr meter, MOS FET Push Pull PA.

Dimensions :8.5 X 7 X 4.5 inches
?
?
Happy Homebrewing / Happy HAMing
?
73

Hi Frank abd thanks for the info. Your comment about removing rust was very interesting. I have already wrapped the rotor in plastic but that didn't help. A direct replacement is on order so I'll grease it well before installation. Thanks again & Merry Christmas & best 73, Pete WW3O

Also, I belive theier is a lithiumj grease that does freeze....check you local auto garage because they too carry grease that doesn't freeze. Putting a warm wrapper around a rotor IMHO really is unnessary unless that the only option open to you.

It is easier to open up the rotor and grease every moving part but remove all rust and make sure you don't have any gear teeth missing as it will throw your direction off.

Just my 2 cents and FYI for an OSCAR 13 user in the mid 90's.

Merry Christmas

Okay Frank. I served last year in Afghanistan with a bunch of Marines. One was a 9-year vet, a lady who was excellent with a 50 cal as used atop a HumVee. I did EOD and she was our protection outside the wire. She was also a whiz at laptop repair. She didn't say much. The first alarm we would get was the 50 cal going off! I was 66 at the time and that sure shortened my life span a bunch!
Later,
Pete Carr

hi,

avoid ordering direct from MFJ,
they just do not know how to run that
part of their business.

Order from one of the larger distributors
that has it in stock for same day shipment.

From: DVC3565@aol.com
Topic: 7380 Message: 7406

I too had some problems with ordering direct from MFJ. Back in April of 2008
I ordered and received a 5-element 2 Meter beam that had the holes for the
driven element drilled 17 degrees off center from the other elements. I
assembled & took pictures of it, and E-mailed them to Customer Service. I actually
received a new main boom, (drilled correctly), before I got the E-mail
telling me it was on the way. Then the day after I got it, they CALLED to confirm
that I got it and was satisfied with the replacement.
This was not my first item bought from MFJ, in fact it was like my 6th item.
However it was the first problem I ever had with them. I for one am very
SATISFIED with how they treated me. I am an ICOM ham, and have had problems with
some of their gear too. No manufacture is 100%. Some "things" slip by, as
they do with car makers too. It's all in how they take care of their problems.
MFJ is not the "Top Shelf" of ham gear, but I have found it to be reliable
AND cost effective for what it does. Not all hams have a six figure income and
40 acres to put up towers & monobanders.
Just my 25 cents worth and support for a company I am GLAD is still around
AND in business.
73,
Dave-KJ4PF

Can NOT agree with that. I have ordered from LOTS of retail, direct and drop and NO ONE is immune from slip ups.
That being said; MFJ customer service is WORLD CLASS!! They SPEAK and UNDERSTAND English and truly seem to care about you and your order.

I have been a HAM for right at 20 years and will say that I have and will continue to be a fan of that company.

What you probably do not understand is that the company uses and has an internship program to teach young kids the ways of business. Something that I truly believe is commendable.

Just my opinion, but I like to give respect where respect is due. Have shook the OWNERS hand at many Hamfests, also.

I have one of their tuners. It refused to work for a while until I opened it and fixed a solder joint. Really shoddy work. I get the impression this is not an isolated incident.

Would still like the antenna meter but don't have the disposable $$.

Same here - been ordering from them for about 20 years - their 'early' days were somewhat rough, but they've come a long way in product development, standing behind their products, and their customer service.

Just recently ordered something that didn't work out for my QTH, sent it back and got a refund in about 4 days - no questions asked,and no hassles. Sorry I can't say that about some other ham equipment dealers...

I'm on a fixed income myself and have to watch every penny.
Next time order from a dealer that can verify that the item is on hand.
Actually dealers usually sell for a little less than diredt from MFJ.
You would think that it'd be the other way around but since dealers buy
in quantity they get special deals that they pass on to their customers.
The fact that they are still in business after all of these years must mean
something. Others have come and gone but MFJ is still around with
affordable equipment and accessories.

I have never had a problem with the things I have bought but NEVER order direct from MFJ. It cost too much , I go through R&L Electronics or GigaParts, the sell at a discount. When I ordered my antenna analyzer form GigaParts it was out of stock in the store so they gave me an additional 10% discount on the entire package, case and accessory pack. I did not complain .

I tried to order everything from someone else. But no one had the antenna. If I had a problem with their products, which I own, Antenna anyalizer, freq counter and the $700 tuner I just got from AES. For about the same money, I could have bought several other antennas, HF verticles are around $400. But I thought I'd give MFJ another try. And they failed, plain and simple. FAILED!!!! I'm not picking on them, I'm stating facts. And if you guys have had good luck, great, I haven't, and I'm stateing facts. Remember no matter how many "atta boy's you get, one Aw$#!+ wipes them all out....Bill N8VWI

Hi guys and Gals,

I've owned an AV620 for about a year, but I don't think a vertical is an antenna for me. So, mine is up for sale. It is still assembled, but will take it down for shipping. CUS only. Or, come pick it up.

<http://www.eham.net/reviews/detail/555> for reviews.

We paid $300.00. I'll let it go for $150, and I'll put new SS screws in the package.

Have a Happy New Year.

Bill,

I think I would ask to speak to the manager or owner. Perhaps they have a direct contact email address. They've been around too long to have this stuff happen. If they have an employee with a problem, whether a trainee or not, they need to be told about it.

Good luck,
Skip KI6GKS

Yes Skip, That is what I intend to do. If necessary, I'm good at pestering people. I've been argueing with the VA for 16 months to get my money straightened out. I'm not trying to get something new, I'm just trying to get what they say they owe me. I guess I'm like that pitt bull with lipstick ;-) I hope everyone has had a fantastic Christmas. And will have a great New Yeaars...Bill...N8VWI

7419. Fw: [ham-antennas] Re: MFJ, what a pain in the ____!!!!

Yahoo group: ham-antennas (2008)
Date: 2008-12-26 03:15:33 UTC
From: Chuck Schultz
Topic: 7419 Message: 7419

MFJ only sells direct to the public as a service to those of us with no immediate access to onr of their dealers for their products. It is not considered good business to compete with your distributers if you are a manufactor. Quite often when purchasing their products at hamfests I have been direct to a dtocking dealer for a better price by the personel manning the MFJ booth only to have the dealer walk over and get said item from the MFJ display to sell to me. To reduce costs items are built in runs of products. When ordering direct you may have to wait for the next run, while ordering at a discount from a dealer will recieve an item off the shelf from stock that was pre-ordered and purchased on spec. To become a stocking dealer requires a considerable investment to start with and a minimum inventory to maintain. I have been using their products for all of my 30 year Ham career and plan to continue the next 30 at least . Chuck Wq5B

Same here - been ordering from them for about 20 years - their 'early' days were somewhat rough, but they've come a long way in product development, standing behind their products, and their customer service.

Just recently ordered something that didn't work out for my QTH, sent it back and got a refund in about 4 days - no questions asked,and no hassles. Sorry I can't say that about some other ham equipment dealers...

Chuck, If I had a problem with their products, I certainly would not have bought a MFJ-998 Auto tuner for $699.95. I just did a search for a MFJ 2990 antenna and MFJ was the only place that seemed to have them. You find me a dealer that has one, I'll order it from them and cancel the order from MFJ...Bill..N8VWI

Chuck, If I had a problem with their products, I certainly would not have bought a MFJ-998 Auto tuner for $699.95. I just did a search for a MFJ 2990 antenna and MFJ was the only place that seemed to have them. You find me a dealer that has one, I'll order it from them and cancel the order from MFJ...Bill..MFJ..

Same here - been ordering from them for about 20 years - their 'early' days
were somewhat rough, but they've come a long way in product development,
standing behind their products, and their customer service.

Just recently ordered something that didn't work out for my QTH, sent it
back and got a refund in about 4 days - no questions asked,and no hassles.
Sorry
I can't say that about some other ham equipment dealers...

From: Greg DeChant
Topic: 7419 Message: 7423

Hi Bill!

I also have a small space for an antenna. If this is your first installation, you will need the Balun and the radial plate. The radial wires don't have to be any certain length, just make them as long as you can and the more wires you use the efficiency will improve.

A vertical antenna utilizes two elements, one is the radiator that is standing straight up, the other element is the radial wires.

In addition to the antenna, radial plate, balun and coax you will need a tuner, which I won't suggest as to whom you should purchase that from.

Topic: 7419 Message: 7424

I have a pretty sizeable investment from them myself. I use only Hy-Gain antennas , I own an Ameritron Al1200 amp , a Al600 amp , the 500 mobil amp, several of their tuners , a 259 ant analzer and the list goes on. I once bought their Atomic watch . The band was too small so I attempted to buy a few extra links . No go , they did offer to return my money . I wore it too tight for awhile and either my wrist shrunk or the band stretched . It kept great time until I attempted to replace the battery. I ended up driving all the pieces and the new battery back into the case with a two pound hammer before taping a quarter to it and throwing it in the trash. I now own another brand Atomic watch and it has a solar cell so I will not need the hammer for any more battery replacements. Chuck Wq5B

ARCALA EXTREMES AT OH8X Finishing the 160m 3el YAGI Monster
:)<http://www.ly4a.com/?p=2499>

Today is the shortest day of the year - only three hours of daylight and as
of yesterday

the Arcala Extremes antenna's last 160M element went up!

After working three weeks straight OH8SR and OH6RM went home for Xmas!

Please note the following technical details;

Tower height 100m

80M and 160M booms 60m

Five (5) 80M full-size elements

You note in the picture that OH8SR and OH6RM are working inside the boom.

Poor OH8SR - with 2nd 160M element he was working in a total fog without
seeing the

ground for 7 hours! He seemingly enjoy working inside of the boom!

The upper slip-ring has such diameter that you can drive thru with Juha's
large Lexus!.

From: wd4elg_base
Topic: 7419 Message: 7428

The 43 foot MFJ vertical is a copy of the DX Engineering antenna, and THAT is a copy of the original Zero-Five verticals 43 footer.

I have the ZF 43 footer and remote tuner and I could not be happier. It absolutely needs radials. However, it works well on a small lot with those radials. I have my radials (24 of them, each 64 feet in lentgh) wrapped around my properly line. The antenna is wrapped in black electrical tape for stealth (my requirements, since I am in a subdivision).

This is not a cheap antenna (it is expensive compared to dipoles, but it is well made). It has a specific purpose - low-angle radiation for long-distance DX. I can tell you that it works extremely well for this use. And the taper design means it is a 43 foot with no guy wires.

I have a detailed review of the 43 foot vertical from Zero-Five on eham.net http://www.eham.net/reviews/review/74121

Array Solutions (reseller) has more details on the 43 foot design. http://www.arraysolutions.com/Products/zero_five.htm#top%20of%20page

It must have a balun and tuner at the shack, or a remote tuner (I picked the remote tuner because I am using 100 watts and I need every ounce of power going into the antenna and not being wasted in the coax).

Tom, NK9W, who owns Zero-Five, is a super individual and can (and does) answer any and all questions (zerofivechicago@...).
Believe me when I tell you I had serious reservations about plunking down my hard-earned spare change for this addition. I was reluctant, but I am quite satisfied.

I have thought several times over the years about putting up a
vertical. I've always heard that verticals were best on the lower bands
-- 40,80, and 160. Are those the bands you use yours on? Or do you
also use it on 10-30? Where does it seem to work best?

Thanks,
Earl

Most dealers do not stock "everything" from a manufacturer. Being a part time employee of an MFJ reseller, I've sold many an item that my store didn't normally stock. We sell it, it generates a purchase order to MFJ, then it's either delivered to our store and re-shipped, or shipped directly from MFJ to the customer. Most of the time, we prefer it to come through the store so that it can be inspected before forwarding to the customer, so that we're sure that we're not shipping blindly and potentially damaged merchandise being delivered.
There are two sides to every story, and I've also met Martin, and can speak for his character. He's a great guy, and I say that not as a reseller of his products (keep business & pleasure separate), but as a fellow ham. I've spoken with him on several occasions, and he's very much in tune to what the ham community says about his products. I'm sure that if you escalate your issue, as you've stated, you'll see good results.

But back to the original point: If a reseller doesn't have it in stock, that doesn't mean they can't get it for you. Usually, when we order, it's shipped next day if they have it in stock, and if not, we're in constant communication with the manufacturers and can give a pretty good response to the customers on expectations.

Hope this helps!

I am a manufacturer of scientific products. I know that sometimes we do not have a product in stock, and therefore the customer must wait some time for delivery. Patience is required. In most cases, it is not a "Life or Death" situation. Sure, it is always nice to buy something and have it in our hands quickly, but it doesn't always happen that way. Life is too short to get upset over such trivial things. Now, if the product is a medication for an illness, then there is cause for concern. There are valid reasons for late delivery and MFJ has always been good to me. Only once did I find a quality control problem from MFJ and it was fixed quickly. You cannot judge a company by one mistake. Anyone who is without fault can throw the first stone.
And, yes, you can get better prices from dealers. HRO has free shipping over $100 purchase and no sales tax. The discount to dealers is not available from MFJ to individual buyers. MFJ pockets that discount for their profit margin when you buy direct. Basically, they pay themselves to do the sale on the phone direct to you. Normal business practice.

Best Regards

Can NOT agree with that. I have ordered from LOTS of retail, direct and drop and NO ONE is immune from slip ups.
That being said; MFJ customer service is WORLD CLASS!! They SPEAK and UNDERSTAND English and truly seem to care about you and your order.

I have been a HAM for right at 20 years and will say that I have and will continue to be a fan of that company.

What you probably do not understand is that the company uses and has an internship program to teach young kids the ways of business. Something that I truly believe is commendable.

Just my opinion, but I like to give respect where respect is due. Have shook the OWNERS hand at many Hamfests, also.

The theory of a vertical being the best depends really on what you want it to do. If you want long haul DX work, then a vertical will work well but they do need radials to work most efficiently unless they are of the half wave variety. If you want mainly close in contacts such as state wide coverage for nets, emcomm work, and traffic handling, then a low horizontal dipole would be better in most cases.

Here's a simple vertical that works well and doesn't cost an arm & a leg - www.w8afx.com and look for the Eagle One Vertical. Its 31' tall and requires a tuner (best if used with an autotuner at the feedpoint such as the Icom AH-4 or SGC-237) and it will work 10 thru 80 meters. SOme folks are using them with coax and a manual tuner in the shack, but I still think the autotuner at the feedpoint is best - that way feedline losses are much less because the coax is operating in a matched condition.

Nothing magical or special about any of the 30', 43' or 65' verticals though - they've been around for years in the homebrew version. The commercial guys just finally caught on !

Rich

Good morning.

I have a 43 foot vertical up homemade and I have One of W8AFX eagle
One up I have work VK and JA wirh 50 watts. they are good for dx.

I have phase these two together and work great. I have work HP V32,
on 75 meter at 3995 and with 50 watts go 47 to 53. I am hopeing to
put up a third one up in a few week when I get back hopeing to get
better dx in JA,VK.

My rig is FT-897d 50 watts ATU is a AT-897 it tunes 10 to 75 to 1.3
to 1 on 3.995. 17 meter work good too. 40 meter is great work 1:1 swr

I will agree with the comments on MFJ being pretty decent about fixing their screw-ups. They may not make top-of-the-line gear, but it works, and on the phone--at least--offered me some pretty savvy technical tips on how to repair one of the tuners. And this from Mexico...they paid for the call. 73 XE1GXG www.barnardbaca.com ? ¡Todo sobre Amor y Sexo! Remember that is a massive 80m 5 el and 160 m 3 el beam, bothe with 60 m long boom - naturally has to take a long time to load such a massive stuff.
Seriously, it took some 15 or more minutes to load. Photos are not hi-res, no great details but we can make out the beams are massive.

People,
You forget that this is just some blokes web page. NOT some high dollar
web site set up to handle 1000's of hits per day.

Even it it was, something as well published and NEW as this will
bring TONS of lookie-loows.

Give the page a rest, it aint going anywhere! Imagine if 1000 people
called your cell phone EVERYDAY just to see if you answer.

It does not matter if you have a TRUE T-3, his site may not be up to the task and
he may be unwilling to spend hundreds of dollars just so you can get a peek at
his hard work.

Do unto other...

hi,

I also own several MFJ items, all worked fine
out of the box and I got what I paid for,
the ordering dept. needs some attention.

Mr. Jun is a real nice guy, he could offshore
all his products and make a lot more money,
however, he has not done this and that is
a good thing.

take a look at the mfj reviews on eham.net
and see for yourself. also parts are sometimes
hard to get from MFJ directly.

even AES has has a customer service problem
this past month, take a look at eham.net
review on aes, they made big error in service
and did stand up to that error on eham.net.

Do you have photos of actual antenna?

The actual antenna/tuner at:

http://groups.yahoo.com/group/Shortwave-SWL-Antenna/photos/album/39551603/pic/714940551/view?picmode=large&mode=tn&order=ordinal&start=1&dir=asc

does not exist. I was doodling. Like what people do
when they think on a peace of paper or scribble, while
talking on the phone.

You might call it a digital doodle.

You are welcome to copy and build the
antenna/tuner.

May you become prosperous in the
coming new year!

No, he is correct. Since the doodling calms the mind, the piece of
paper becomes a peace of paper

7451. shortned dipoles?

Yahoo group: ham-antennas (2008)
Date: 2008-12-27 13:45:31 UTC
From: wa7dxz@aol.com
Topic: 7451 Message: 7451

Looking ofr opinions on some commercial shortened dipoles.... anyone use them? Comments? Looking for a shortened 80-10 dipole... how much does the performance suffer? The only thing I need 80 for is Navy MARS...mostly i work 40, and some 30, and 10.
I was even thinking of going to a 40 meter dipole, and checking into MARS on that, with tuner...

I've had good luck with the Alpha Delta DX-CC. Works better on all
bands than my G5RV that was coil shortened. Only give about 100KHz 2:1
BW on 80/75M and SWR is a little high on 15M since it using 3 harmonic
of 40 for that. I use mine with a LDG tuner and it works on all bands
but SWR on the antenna side is way high on 60M.

From: Dan Schaaf
Topic: 7451 Message: 7454

I just replaced my G5RV Inverted V with the Alpha Delta DX-LB as an inverted V. So far it seems to work OK, but the bands 160 and 80 have not been too active, so I am still evaluating it. It works well on 60 meters. I use a tuner in the shack.

Hi all from new mwmber,

Just recently saw an ad from Hy-gain for their 6160 43' vertical which according to them needs at least one radial to work. I live on a lot with not alot of room for a full sized dipole to cover (160)80-10m. I like the looks of this vertical and may get one this spring. Then I see an ad from MFJ which nshows what looks to be the same antenna! What gives? Anyone answer this? Thanks.

From: John Lewis
Topic: 7453 Message: 7457

It's difficult to say what the problem is without your doing a few basic tests to see where the interference is coming from.

I'd start with disconnecting the antenna from the radio. Does the interference disappear? If so, it's probably an outside source coming in through your antenna. With the antenna off if you still get the noise, it's in all probability locally generated inside your home.

If it's inside your home, try flipping each individual circuit breaker and see if the noise stops. If it does, it's something associated with that breaker, unplug the items one by one and see which is causing the noise.

Use a portable AM radio set to an empty freq on the lower end of the dial and walk around holding the radio close to sources you think may be causing the noise until the noise increases as you test an individual source.

The above should get you started and the results give the members of the group more to work with...

Thanks.

To start, what band(s) is affected by your static?
What type of antenna are you using?
Have you tried running the receiver on a battery and shutting off power
to the house?
Have you checked the continuity of the shields of any coaxial jumpers?

Have a Happy New Year.

7460. Re: Vertical Yagi for HF ?

Yahoo group: ham-antennas (2008)
Date: 2008-12-27 16:55:11 UTC
From: Paul
Topic: 6385 Message: 7460

All other things (e.g. height of the center of radiation of the antenna) being equal, polarization makes no difference in the Take Off Angle.

When measuring (or calculating) the TOA on a vertical antenna it is usually assumed that the antenna is a monopole sitting on the ground.

If the vertical antenna is a dipole, a few wavelengths above ground the TOA would be the same as for a horizontal dipole at the same height above ground.

7461. Re: [ham-antennas] Re: Vertical Yagi for HF ?

Yahoo group: ham-antennas (2008)
Date: 2008-12-27 16:59:47 UTC
From: Joe
Topic: 6385 Message: 7461

That is far different that many for over 30 years of charts I have seen. especially at lower altitudes, not too many people can put 20 meter beams many wavelengths above the ground, most are lucky if they get 1 wave above.

7462. Another 43 ft antenna Q

Yahoo group: ham-antennas (2008)
Date: 2008-12-27 17:06:30 UTC
From: Rick
Topic: 7462 Message: 7462

With many 43ft type antennas out there,DX Eng through MFJ. What separates them from each other, from the cost view. One is up to 400USD and the other is below 300USD. Why would someone,like myself, pay more for one rather than getting the inexpensive one. The Hygain and the MFJ look identical including the advertisement pictures. Just wondering since we are on this subject,

Rick/WA6ES

7463. RE: [ham-antennas] Another 43 ft antenna Q

Yahoo group: ham-antennas (2008)

I have the DX Engineering. Look for thickness and grade of the aluminum used. Consider the overall diameter and whether there is a fast taper (keeps it light and rigid) and the quality control reputation of the manufacturer. I painted my camo colors, used the DX engineering radial plate and tilt base and it does well in moderate wind but I can easilty bring it down in literally 1 minute for expected lightning or storms (buy the knurled knobs for the tilt base) . These all suffer from being non-resonant and as I just found out they like a lot of coax feedline at least 100- but better 150 feet so don;t be cheap on low-loss coax... I have about 40 feet coiled up like a poor man's choke right after the tuner. Figure you will have significant losses on 80 and 160m so get an amp

least 100- but better 150 feet so don;t be cheap on low-loss coax... I have
about 40 feet coiled up like a poor man's choke right after the tuner.
Figure you will have significant losses on 80 and 160m so get an amp

Those non-resonant, 43 foot verticals, could use an remote antenna tuner
at the *feed point* like my doodle at:

http://groups.yahoo.com/group/ham-antennas/photos/album/402385040/pic/2087035607/view?picmode=large&mode=tn&order=ordinal&start=1&dir=asc

I wonder, outside a *water proofed* MFJ-998, if anyone makes a remote
tuner that handles 1500 watts and mounts at the feed point of the antenna?
Did I say under $2000?

Best regards.

>To start, what band(s) is affected by your static?

i can hear it on all bands

>What type of antenna are you using?

i have the cobra 10 -160 meter dipole , the top is about 50 ft up and
the ends are at least 20 ft off the grd each leg
I have a G5rv and a 10 meter tuned Antron , and I have a 5BTV, it
seems to come in on all of them.

>Have you tried running the receiver on a battery and shutting off power
>to the house?

2 of my radios i run on recharged deep cells, i unplug the charger
when i turn on the radios, still get the static

>Have you checked the continuity of the shields of any coaxial jumpers?

all coax jumpers are in good shape

>Have a Happy New Year.
>
>Steve/WM5Z

Thanks ALL For your help here... any advice I'll try as soon as
weather & work permits

Could it be coming into the house from the power lines???

I use a MFJ-927 and it works great, but it's only 200 watts.

I have it mounted inside a plastic container I got a Wallmart.
Power comes in on the center conductor of the coax.

Neil Harvey?? AC6YO

From: Frank MacKenzie-Lamb
Topic: 7453 Message: 7467

Power lines up here in N.E. are notorious for their noise. I vote for the power line noise unless you can gey a UPS the cuts out noise. Failing that, tune your car raio to the lowest AM setting (i.e. 530 AM) and turn up the volume...drive a couple of miles up and down your block/area. If there's an insulator that cracked or out, you will hear that static pick up in volume as you approach it and decreased when you leave the area. A broken insultor could concieveably be quiet a distance from your home but if on the same circuit as yours, I'd call the power company as they have to fix it at no expense to you.
Other possible is interface from a nearby ham.
Good luck

Frank

It could be the fact that MFJ owns Hy-gain just as MFJ now owns Ameritron.

Hi all from new mwmber,

  Just recently saw an ad from Hy-gain for their 6160 43' vertical which according to them needs at least one radial to work. I live on a lot with not alot of room for a full sized dipole to cover (160)80-10m. I like the looks of this vertical and may get one this spring. Then I see an ad from MFJ which nshows what looks to be the same antenna! What gives? Anyone answer this? Thanks.

Hi, Ken- I like John's idea of flipping individual breakers and note which one quiets the static- Of course, if the breaker you flip goes to your gear, then the quiet doesn't mean you located it! (HI!)
Seriously, I've found this from arcing power pole insulators. A call to the power company would be wise,and they appreciate a heads up before it totally goes bad. These bad pole arcs will be worse in the early morning,late evening due to moisture,dew settling. Quieter in the day.

Semper paratus, Earl (for those non-Coast Guard people, it is the Latin motto for Coast Guard and it means ALWAYS READY)

Earl, the long-winded answer is "it depends." I like having options, and here is the logic I use. I am mostly 100 watts on CW. My goals are to increase my DXCC count to 300 (currently at 250). I also want 9BDXCC.

For all HF bands I have a Buckmaster off-center-fed dipole. This allows me some non-directive medium and high angle capabilities on the lower bands (Caribbean and SA DX) for 40 and 80, but has also given me some good long distance DX when the arrival angle was above 15 degrees (uncommon, but not unheard of, see ARRL Antenna Handbook on signal angle of arrival). The Buckmaster is a good all-around wire antenna, built like a tank, gives me all bands (some with a tuner).

Also for all HF bands, I have an OUTback er Outreach. Not cheap, but very portable and works well, esp on 30 (ZL8R, others).

For 10, I have a Ringo Ranger vertical, but it is disassembled since 10 is only open for sporadic E prop in the summer.

For 17, I have a Par EndFedz half-wave wire. Not much I can hear on 17 with it these days due to poor prop and reduced actvity (relatively), but I have worked about 75 countries since summer of 2007.

For 20, I have a very costly but very productive hex beam. It is on a 32 foot mast, and it rocks. 20 is where the big boys hang out, and

the best all-around DX band. So I decided to splurge and get a durective antenna. WHOA. What a difference! It is wirth every penny. And it is way less visible and smaller than a yagi.

For 30, I have another Par EndFedz which has helped me get to 100 entities worked.

For 40 and 80 I have a Cushcraft MA8040V which works well on 40 (YB1A on 40 meter longpath 3 years ago, lots of EU with 5 watts) and fair on 80 (although I did nap VK9DWX last winter). It is a compromise on 80, but it did get me to 100 worked.

I also have a Par EndFedz for 40, in the shape of an L. It works surprisingly well for a wire (including 3B7C and 5A7A).

Then there is the 43 foot multibander. I bought it to give me low-angle radiation on all bands. I wanted better performance on 80 over the Cushcraft, and 160. I was hoping for some better performance (just a tad) on 40, and then when the sunspots return next year in force I will be ready. Unfortunately, I cannot get on to 160 except with the Buckmaster. It is not designed for 160, but my Kenwood TS570 does tune it and I have worked 15 countries with it. But on 80 it sure does better than anything else. I worked my first JA and ZL on 80 last month (I never even heard these countries on 80 before!). And I worked some tough spots on 80 through pileups: EL, A2. My count is now up to 120 on 80. On 40 it certainly has busted some serious pileups, including VQ9. Nothing else new yet, but I already had 190 worked on 40. On 20, I have easily worked all over, but as mentioned above my main antenna is the hex beam which cannot be beat with a vertical. On 17, 15 I have worked some DX but nothing new (conditions). Nothing worked on 12 or 10 but I have not spent any time on those bands.

I also like switching back and forth between wires and verticals to find the best way to reach a station. This may make a difference with my 100 watts, esp if the station is less than 5000 km distant.

Hope this helps

Mark Lunday

Hi Ken,
If you could please be a little more specific on the noise you are hearing or if possible record it. I would be glad to listen to it and tell you what I think. I don't consider myself an expert but I am a lineman and love to figure these problems out. If it is coming from the power lines, there can be a multitude of things wrong. There are certain characteristics of the noise that can help determine the source of the problem..Sometimes..There are a few things that I would concentrate on to begin with.Dead end Bell Insulators. Those are the insulators that are usually installed horizontally on the side of a cross arm where a power line dead ends or changes direction. If you have these near the house and are made of porcelain and metal I would ask your power company to take a look and listen with their gear if they have it.If that would be the source of the problem, ask for them to replace them with a polymer insulator sometimes called epoxilators.The old
style dead end bells can be quite noisy.Steel sandwiched between porcelain.Electricity will actually discharge along the surface of the bells due to an oxidation layer. Rain actually tends to quiet them down in my findings. Cleaning them and installing clips on the connection point to the pole is only a temporary fix.Loose hardware also can make noise.Such as through bolts, ground wire staples.The time of the noise can have allot to do with weather as well. Loose tie wires holding primary wire to Pin insulators is fairly common as well. That is an easy fix for them.Two other sources of the most common power line noises are Fuses and Lightning arrrestors. The fuses and arrestors are near transformers and other distribution gear that at some point may need to be isolated from a ciruit. Most problems are allot easier to fix than to find though. Faulty gear a long way down the line can radiate in some strange un explainable places.

Again, if possible record the noise and send it my way. I will be glad to do what I can for you and hopefully point you in the direction.
Jim

Hi, Ken- I like John's idea of flipping individual breakers and note which one quiets the static- Of course, if the breaker you flip goes to your gear, then the quiet doesn't mean you located it! (HI!)
Seriously, I've found this from arcing power pole insulators. A call to the power company would be wise,and they appreciate a heads up before it totally goes bad. These bad pole arcs will be worse in the early morning,late evening due to moisture,dew settling. Quieter in the day.

I have several radios in my room, all are hooked to several 10ft
ground rods I got from the electrical outlet, and im still having
problems with static almost 24/7 can you guys give me hints on
what to try and what /where to look for this stuff, im tired of bacon
frying every day
Thanks

7474. Re: [ham-antennas] ALPHA DELTA DX-LB

Yahoo group: ham-antennas (2008)
Date: 2008-12-28 00:16:09 UTC
From: DVC3565@aol.com
Topic: 7472 Message: 7474

I have a DX-LB up. I have used it for 4 months. It is at 35 foot on the lower side of my back yard, 22 foot on the upper side of the backyard. It is supported on the side of my tower at 40 foot, which makes it a some what of a small Inverted V.
I feed this with an Icom IC-735 with the AT-150 Auto tuner. The antenna is set from the factory to be resonate at 1.850. My tuner allows me to work 1.775 to 1.880 under 2 to 1 SWR. I am sure IF I could put it up higher the bandwidth would improve some.
Since I put it up, I have worked 23 states & 11 country's on 160...Barefoot!
And this is the first time I have worked 160 since I became a ham in 1966.
But note, you will have a lot more static AND lightning "crashes" on 160.
Good Luck es happy Hamming.

Dave-KJ4PF

Semper paratus, Earl (for those non-Coast Guard people, it is the Latin motto for Coast Guard and it means ALWAYS READY)

Earl, the long-winded answer is "it depends." I like having options, and here is the logic I use. I am mostly 100 watts on CW. My goals are to increase my DXCC count to 300 (currently at 250). I also want 9BDXCC.

For all HF bands I have a Buckmaster off-center-fed dipole. This allows me some non-directive medium and high angle capabilities on

the lower bands (Caribbean and SA DX) for 40 and 80, but has also given me some good long distance DX when the arrival angle was above 15 degrees (uncommon, but not unheard of, see ARRL Antenna Handbook on signal angle of arrival). The Buckmaster is a good all-around wire antenna, built like a tank, gives me all bands (some with a tuner).

Also for all HF bands, I have an OUTback er Outreach. Not cheap, but very portable and works well, esp on 30 (ZL8R, others).

For 10, I have a Ringo Ranger vertical, but it is disassembled since 10 is only open for sporadic E prop in the summer.

For 17, I have a Par EndFedz half-wave wire. Not much I can hear on 17 with it these days due to poor prop and reduced actvity (relatively), but I have worked about 75 countries since summer of 2007.

For 20, I have a very costly but very productive hex beam. It is on a 32 foot mast, and it rocks. 20 is where the big boys hang out, and the best all-around DX band. So I decided to splurge and get a durective antenna. WHOA. What a difference! It is wirth every penny. And it is way less visible and smaller than a yagi.

For 30, I have another Par EndFedz which has helped me get to 100 entities worked.

For 40 and 80 I have a Cushcraft MA8040V which works well on 40 (YB1A on 40 meter longpath 3 years ago, lots of EU with 5 watts) and fair on 80 (although I did nap VK9DWX last winter). It is a compromise on 80, but it did get me to 100 worked.

I also have a Par EndFedz for 40, in the shape of an L. It works surprisingly well for a wire (including 3B7C and 5A7A).

Then there is the 43 foot multibander. I bought it to give me low-angle radiation on all bands. I wanted better performance on 80 over the Cushcraft, and 160. I was hoping for some better performance (just a tad) on 40, and then when the sunspots return next year in force I will be ready. Unfortunately, I cannot get on to 160 except with the Buckmaster. It is not designed for 160, but my Kenwood TS570 does tune it and I have worked 15 countries with it. But on 80 it sure does better than anything else. I worked my first JA and ZL on 80 last month (I never even heard these countries on 80 before!). And I worked some tough spots on 80 through pileups: EL, A2. My count is now up to 120 on 80. On 40 it certainly has busted some serious pileups, including VQ9. Nothing else new yet, but I already had 190 worked on 40. On 20, I have easily worked all over, but as mentioned above my main antenna is the hex beam which cannot be beat with a vertical. On 17, 15 I have worked some DX but nothing new (conditions). Nothing worked on 12 or 10 but I have not spent any time on those bands.

I also like switching back and forth between wires and verticals to find the best way to reach a station. This may make a difference with my 100 watts, esp if the station is less than 5000 km distant.

Hope this helps

7476. 10 meter wire antenna??

Yahoo group: ham-antennas (2008)
Date: 2008-12-28 01:53:47 UTC
From: wa7dxz@aol.com
Topic: 7476 Message: 7476

I want to work only Ten meters...and I want to use a wire antenna,,, some type of maybe inverted vee. I was thinking... tell me if I am wrong here...I have been told that it is hard to make a half wave dipole resonant on a full wave freq... inother words, a 40 meter antenna wont tune well on 20, but tunes well (close anyway) on 15... SO...
what if I took the measurements of a half wave dipole for Ten,,, then found the longest 1.5 wave multiple I could fit into my yard....would that give me any theoretical "gain" over just he half wave dipole? Longer wire, better signal? And then fine tune it to resonate on the freq I want on Ten?
So at 28.1 mhz,,, a half wave is 16.5 ft,,, X 3 = 50 ft... X 5 =83 feet... roughly 42 feet on a side... I could get that into my yard...
Would the 83 footer (which is now resonant on 28.1) work better than a standard quarter wave, it should, shouldn't it?
OR... put up a 100 foot dipole, and use a tuner... which is better, the resonant 83 footer or the 100 footer that I have to put through a tuner...

Bob

Good logic, but it does not quite work like that.

You could build a 64 foot doublet and feed with 450 ohm ladder line and this would work on several bands. But the gain comes from directing the energy, which happens in a yagi design.

My first question is, why 10 meters? We are at the bottom of the sunspot cycle and there is virtually no activity (except for summer sporadic E and some contests). Why not 20 or 40 meters?

With what you are telling me the source of your noise is external to your house, but ONLY if you totally removed power to your house at the meter entry switch and ran the radio from the battery.

The next step would be to go mobile and see if you can find it's location outside the house.

If it is power line noise, and you can locate the source, the service company can fix it. If it is something like a store's neon sign, you might have to negotiate with them to get the problem fixed.

The ARRL has several informative pages on this problem both in their books and on their web site. For assistance, I also recommend that you get assistance from your local ham radio club. Many of the members might already have gone through what you are.

Have a Happy New Year.

7479. RE: [ham-antennas] 10 meter wire antenna??

Yahoo group: ham-antennas (2008)
Date: 2008-12-28 03:14:24 UTC
From: Richard Schmuke
Topic: 7476 Message: 7479

Bob , it will work but if you are going to use coax you will need to make it a little longer. The wire has an end effect so the last 1/4 wave is figured at 234/FMH but the other two are closer to 247/FMH.

You could go out to ☐5/8 wave each side as a EDZ for more gain with a ladder stub feed then coax to the shack.

7480. Re: [ham-antennas] 10 meter wire antenna??

Yahoo group: ham-antennas (2008)
Date: 2008-12-28 12:39:27 UTC
From: Siegfried Jackstien
Topic: 7476 Message: 7480

it depends ..... you only want to use it on 10 so the resonant one will be a bit better
no tuner needed so no tuner losses

if you want to go multiband you should use ladderline
if you have high swr on the feedingline you will have much loss in the coax so ladderline
is better

the resonant one (83 footer) will have some gain but narrower beamwith
so maybe less stations to work with..

what about a cb antenna ??? shorten it a bit and you are ready for 10m
there are cheap yagis for cb on the market and can easy be cutted to work on 10

7481. End fed matching network problems

Yahoo group: ham-antennas (2008)
Date: 2008-12-28 13:29:36 UTC
From: Kim
Topic: 7481 Message: 7481

I'm trying to build a matching network for a one half wave end fed antenna and if fact have built three over the past two months but neither has resonated. I figure it's about time to ask for help. The antenna wire runs down to the stator (hot side of the capacitor). The capacitor is in parallel to an iron core form that has about 15 turns on the primary, with 2 turns on the secondary, one end connected to the inner conductor and the other to the shield of the coax leading to the radio. Each way I do this I get infinite impedance at all test frequencies no matter how I tune the capacitor.

Question: Does the coil have to be wound with magnet wire? I've seen pictures of coils wound with 22 gauge hookup wire. The other possibility is I am misinformed about the connection points on the capacitor. Any assistance would be appreciated.

From: Richard Schmuke
Topic: 7481 Message: 7482

I am not sure about your ☐Iron Core Form☐. I assume you mean iron-powder , you did not say if it is a rod or toroidal form. You also must have the right material type for the frequency you are working with. Many types of iron core forms are for power supplies and won☐t work with radio frequency RF. A rough guide is the red or type #2 ones for most HF bands , you can use the yellow for the higher HF bands.

Magnet wire is not needed. It is handy to hold it shape while making on the smaller 100 to 300w sizes , I used Teflon coated stranded wire on the Kw sizes. For a T-106 or T-200 size I use magnet wire .

A ladderline question... I have a Rohn type tower,,, I'd like to put a dipole on top of it, and use ladderline...I am worried about the tower affecting the ladderline.
How far do I have to off set the ladderline from the tower, I'd like to bring it down the side of the tower...I assume that encasing it in PVC pipe would do no good either. ?
If I have a 35 ft tower, and bring it down at an angle away from the tower...how far away is the minimum I could get by with? Two feet? Less?

7485. Telescoping Multiband Omnidirectional Vertical Antenna Idea - Is it workable?

Yahoo group: ham-antennas (2008)
Date: 2008-12-28 16:56:03 UTC
From: kugellagers
Topic: 7485 Message: 7485

Hello,

First post here. All things RF related have been one of my many hobbies since I received an old 5-tube 1950's Zenith AM radio from my grandmother when I was a kid. I like old tube communication equipment and old amture radios as well as the new equipment. I readily read papers on antennas and have constructed various SW, 10m, CB, WiFi, MURS antennas over the last few years. I am currently studing for the Techicians ham license.

Anyway,

My wife does not want a huge forest of antennas on our roof and I really do not either. I have been mulling over the idea of constructing a 1/4 wave omnidirectional vertical multiband telescoping antenna that I can raise through the roof when I want to Rx/Tx in 6m-20m once I get my ham license or just do a little light monitoring in the SW and other bands with my SP-600. The idea is to construct the antenna out of copper and brass tubing run up through a 2-floor open space we have in between the walls and raise and lower it to various 1/4 wave heights by a pully system. The intended radiating lengths will be adjustable between roughly about 6ft and 24ft.

The coax connection will be on the roof and will make contact with the radiating portion of the antenna above the connection by means of a spring loaded contact I have devised. There will be a ground/radial system with various 1/4 wave radials for the different bands arrayed just below the coax contact point on the roof (I have used this with good success for simple 1/4 wave 11m (and MURS)roof-antennas - based on theory by Jerry Sevick). I intend for the remainder of the non-radiating antenna (below the connection point)to pass down into a PVC pipe which itself is inside a larger diameter steel electrical conduit that it well grounded. I intend to adjust the frequency band and SWR for each band by raising and lower the antenna as mentioned previously. The impedance of the 1/4 wave antenna should be around 50 ohms with adequate number of 1/4 wave radials.

Will the pipe within pipe design properly shield the unused portion of the antenna from radiating? Will the antenna only radiate above the feed point that is not encased inside the other pipe? Is my thinking on using the PVC within steel conduit to shield the unused portion of the antenna correct for what I would like to do?

I do not want to buy an antenna and enjoy the tinkering of coming up with some new design - heck that's half the fun the RF hobbies.

Please let me know if any clarification on what I am describing is needed.

Thanks,
John

Not to be too picky, but effective gain can come even from a simple dipole by hanging it high. This lowers the takeoff angle and radiation off the ends of the wire making it less omnidirectional.

Bob,

I have no empirical information but from my reading I think they say it needs to be 3 times the width of the ladder line away from metal objects. I would guess that 6" would be adequate.

Someone said that gain comes from directing the signal...(yagi idea) very true, but it simply makes sense that you hear more with more wire... I can't imagine anyone saying that you hear as well with a one foot wire antenna as a 83 foot wire antenna... in other words, I still think, common sense tells me, that a 5 WL WL dipole might hear more than a .5 WL dipole.
But again, I could be wrong.
But again, like someone said, why not just go with my 83 feet, feed it with ladderline, and a tuner, and have all band capability. That is probably the best answer.

All depends on where you want to listen, Yes a longer antenna will have
Gain, but in only certain directions. At a sacrifise to other directions.
The best example I got more than 30 years ago was this.

Concider your signal on transmit. the recieve pattern is exactly the
same by the way , it can not be different.

You have "X" amount of power. Period,

The isotropic antenna, (does not exist) radiated equally in all
directions, but a diploe has apattern looks like a figure 8 broadside
to the antenna. or in a 3 D model it looks like a doughnut.

A 1.5 wave dipole has gain yes, and is resonant too, but the pattern
now looks like a 4 leaf clover. So instead of max gain being broadside
to the antenna, it now has to lobes that are like 45 degrees to each
side of the dioploe. and max sig is no longer broadside to the dipole.

Extending the wire even longer starts to split these lobes into further
lobes and further towards the end of the diploe.

All this keeps concentrating the signal into a smaller and smaller
area, hence the gain.

r think of it this way,, think of you signal as water from a hose.

say your power is equal to 1 gallon per minute,

With a sprinkler head attached to the end of the hose, you have a wide
pattern of the "Power" being spread out evenly over a wide area. (the
dipole) but change the pattern to concentrate the water into a more
tight stream, (fire hose adapter?) the apparant power is much stronger
now. (In only one direction) still same popwer output 1 gallon per
minute. but it seems stronger and it is stronger in the desired

direction. at a sacrifise to other directions. Just like the yagi.

Anytime you have "Gain" you Must loose signal in other directions.
period. you can not create more energy.

>But again, like someone said, why not just go with my 83 feet, feed it with

Hello John,

Glad to hear from someone who would rather build than buy
,for me that is the fun part.

I am not real clear on your feeding point for your antenna but if you are thinking about a sliding feed point, say a roller or a BeCu spring, you can make it work at a set frequency at the point of highest extension but if you lower the antenna from the set point that is resonate the unused part becomes a variable capacitor to the grounded pipe EMT it will be in . I don□t think that will work for transmitting but I am not sure, any ideas guys???.

Rich , KDØZZ

Subject: [ham-antennas] Telescoping Multiband Omnidirectional Vertical Antenna Idea - Is it workable?

Hello,

First post here. All things RF related have been one of my many hobbies since I received an old 5-tube 1950's Zenith AM radio from my grandmother when I was a kid. I like old tube communication equipment and old amture radios as well as the new equipment. I readily read papers on antennas and have constructed various SW, 10m, CB, WiFi, MURS antennas over the last few years. I am currently studing for the Techicians ham license.

Anyway,

My wife does not want a huge forest of antennas on our roof and I really do not either. I have been mulling over the idea of constructing a 1/4 wave omnidirectional vertical multiband telescoping antenna that I can raise through the roof when I want to Rx/Tx in 6m-20m once I get my ham license or just do a little light monitoring in the SW and other bands with my SP-600. The idea is to construct the antenna out of copper and brass tubing run up through a 2-floor open space we have in between the walls and raise and lower it to various 1/4 wave heights by a pully system. The intended radiating lengths will be adjustable between roughly about 6ft and

24ft.

The coax connection will be on the roof and will make contact with the radiating portion of the antenna above the connection by means of a spring loaded contact I have devised. There will be a ground/radial system with various 1/4 wave radials for the different bands arrayed just below the coax contact point on the roof (I have used this with good success for simple 1/4 wave 11m (and MURS)roof-antennas - based on theory by Jerry Sevick). I intend for the remainder of the non-radiating antenna (below the connection point)to pass down into a PVC pipe which itself is inside a larger diameter steel electrical conduit that it well grounded. I intend to adjust the frequency band and SWR for each band by raising and lower the antenna as mentioned previously. The impedance of the 1/4 wave antenna should be around 50 ohms with adequate number of 1/4 wave radials.

Will the pipe within pipe design properly shield the unused portion of the antenna from radiating? Will the antenna only radiate above the feed point that is not encased inside the other pipe? Is my thinking on using the PVC within steel conduit to shield the unused portion of the antenna correct for what I would like to do?

I do not want to buy an antenna and enjoy the tinkering of coming up with some new design - heck that's half the fun the RF hobbies.

Please let me know if any clarification on what I am describing is needed.

Thanks,
John

A ladderline question... I have a Rohn type tower,,, I'd like to put a dipole on top of it, and use ladderline...I am worried about the tower affecting the ladderline.
How far do I have to off set the ladderline from the tower, I'd like to bring it down the side of the tower...I assume that encasing it in PVC pipe would do no good either. ?
If I have a 35 ft tower, and bring it down at an angle away from the tower...how far away is the minimum I could get by with? Two feet? Less?

7500. new 160m dipole project

Yahoo group: ham-antennas (2008)
Date: 2008-12-29 03:47:43 UTC
From: ke4vyn
Topic: 7500 Message: 7500

The plan is for a 160m dipole 260 feet long up in the air at the 80 foot mark.

I'm going to feed it with 600 ohm true ladder line the height of the 80 feet. Then use a air choke made of 9913 coax wrapped around 6" PVC pipe to be able to run the coax into a Ameritron ATR-15.
Going to use the wire mostly on 160/75 and one of the questions is should I use a balun for this project?

I the balun I am thinking is a 600/50 4KW military air cooled that I would put at the bottom of the 600 ohm ladder line feed which is 80 feet below the feed point.

I live on a rocky hill side and will point this NE/NW from central Alabama.

Thoughts would be appreciated. I have 1000 feet of #12 copper stranded and one thought would be doubling or even tripling the wire for more band width.

Ideas?

I like to consider antenns gain as the analogy of the 100 watt light bulb on a pole. Now, place a reflector at the back side. A lot more of your yard is illuminated in that direction,therefore a gain. But, this is the same 100 watt bulb,same power output,simply directed more one way, and reflected from another.

7502. G5IJ Polar Plot Please!

Yahoo group: ham-antennas (2008)
Date: 2008-12-29 17:54:51 UTC
From: Chris Moore
Topic: 7502 Message: 7502

Has anybody got a Polar Plot for a G5IJ at 20feet agl.
The antenna is 20 meters of wire 300 ohm ribbon feeder.
Bands needed are 80m 40m 20m.

Any help be great....

7503. Connecting the MFJ-998 tuner to the antenna feed point

Yahoo group: ham-antennas (2008)
Date: 2008-12-29 19:51:33 UTC
From: Tom Gleeman
Topic: 7503 Message: 7503

Hello Group,

Has anyone tried putting the MFJ-998, 1500 watt,
auto tuner in a water proof box and connecting the
antenna terminals to the antenna feed point?

See doodle at:
http://groups.yahoo.com/group/ham-antennas/photos/album/402385040/pic/1934505810/view?picmode=large&mode=tn&order=ordinal&start=1&dir=asc

Cheers.

Yahoo group: ham-antennas (2008)
Date: 2008-12-29 20:48:46 UTC
From: Jerry Stern
Topic: 7503 Message: 7505

I would be surprised if it worked well on true 'auto'. You would also need to have some ability to remote control it for manual adjustments. I have the Palstar AT-AUTO and though it works great, when there are significant changes to my ground radial system (for my 43' Vertical) such as heavy rainh, melting snow and the the opposite a very dry spell, the "average" settings in memory are not sufficient to allow the auto-tuner to hunt down the best SWR... it will 'time out'. At least on the Palstar I have to find the right ballpark manually every now and then and then let the Auto mode fine-tune and re-memorize it. I would be curious if the MFJ autotuner was more autonomous under these kinds of circumstances... With the AT-AUTO I can remote control everything via RS-232 but RS-232 specifications I recall are limited to runs of shielded wire for 50' or less .

Please let me know how you make out

From: Callum m0mcx
Topic: 7500 Message: 7506

Lee,

If you're feeding it with ladder line via a tuner then the only reason to doubling or tripling the wire will be to strengthen it. Forget it - save the rest for another day and keep it on the reel. Regarding bandwidth, since you have a tuner - it won't matter.

Your comment doesn't mention how long the ladder line is so I can't comment about the balun too much, however I would recommend one. You will have some fiddling with impedances, but I'm sure you are already aware of this!

Cheers,

Callum McCormick

Sent: 29 December 2008 03:48
To: ham-antennas@yahoogroups.com
Subject: [ham-antennas] new 160m dipole project

The plan is for a 160m dipole 260 feet long up in the air at the 80 foot mark.

I'm going to feed it with 600 ohm true ladder line the height of the 80 feet. Then use a air choke made of 9913 coax wrapped around 6" PVC pipe to be able to run the coax into a Ameritron ATR-15.
Going to use the wire mostly on 160/75 and one of the questions is should I use a balun for this project?

I the balun I am thinking is a 600/50 4KW military air cooled that I would put at the bottom of the 600 ohm ladder line feed which is 80 feet below the feed point.

I live on a rocky hill side and will point this NE/NW from central Alabama.

Thoughts would be appreciated. I have 1000 feet of #12 copper stranded and one thought would be doubling or even tripling the wire for more band width.

Ideas?

Wal-Mart sells plastic tubs that are perfect for this. The one I used is
the one that says it fits under a bed.

I put 4 holes in mine. RF in, RF out, DC in and ground. Sealed the holes
with hot glue works fine.

Have a Happy New Year.

For me, I set it up on my favorite portions of the bands. Once it was trained, I never have to touch it. Personally, I think this is a marvelous tuner. I also own the baby predecessor. It has to be told to retune often. Not what I would want for a remote tuner.

Have a Happy New Year.

7511. Hello New to the group, new Ham

Yahoo group: ham-antennas (2008)
Date: 2008-12-29 22:37:02 UTC
From: Gene Dunford
Topic: 7511 Message: 7511

Hi KE7WNX (Gene) here, I received a LDG auto antenna tuner as a present.. I have not mounted any antennae, never used an antenna tuner. I am sure when I learn what questions to ask, I will have a bunch. I hope to set up the grounding rods mount the antennae and turn on the ICOM 706MKIIG; with great hopes for Mid February. I see that with my purchase of the antenna tuner I get a free antenna...

"Purchase any LDG autotuner priced over $149 (suggested list price) between September 15, 2008 and January 31, 2009 and receive a free Dipole Kit buildable for 20, 17, 15, 12, 10, or 6 meters. Download the Dipole Kit Rebate Form and mail it with a copy of your sales receipt to LDG.Be sure to check out the manual for the Free Dipole Kit in the Support/Manuals section of our website (click Here for the manuals page) ."

So I will have two HF antennae to run thur the tuner. I have a home brew multi frequency antenna I bought from a club member LVRAC. Looking forward to passing the general test by the time I have the radio set up.

Stay tuned, I will be asking something stupid when I learn enough to ask stupid questions.

Hey Callum,
Long time my friend. Hope all is good in sister B'ham.

This is the balun http://cgi.ebay.com/ws/eBayISAPI.dll?ViewItem&item=110314062973&ssPageName=ADME:X:RTQ:US:1123<http://cgi.ebay.com/ws/eBayISAPI.dll?ViewItem&item=110314062973&ssPageName=ADME:X:RTQ:US:1123>
I have one like it. Thing cost like 3000.00 from maker.

Anyway, the ladder will be about 70 - 80 feet long. Up a tree to the main pulley. The balun will be mounted on the side of the house and a coax running inside thru a air choke.

What ya think?

Lee

Hi Dan, K3ZXL and the Group,

The MFJ-998 has an automatic mode the tunes
when you key the transmitter and a semi-automatic mode that
tunes when you push the "Tune" button on your transceiver.

I like to use the "Tune" button on my transceiver.
It's closer to my hand.

Cheers.

Hi KE7WNX (Gene) here, I received a LDG auto antenna tuner as a present.. I have not mounted any antennae, never used an antenna tuner. I am sure when I learn what questions to ask, I will have a bunch. I hope to set up the grounding rods mount the antennae and turn on the ICOM 706MKIIG; with great hopes for Mid February. I see that with my purchase of the antenna tuner I get a free antenna...

"Purchase any LDG autotuner priced over $149 (suggested list price) between September 15, 2008 and January 31, 2009 and receive a free Dipole Kit buildable for 20, 17, 15, 12, 10, or 6 meters. Download the Dipole Kit Rebate Form and mail it with a copy of your sales receipt to LDG.Be sure to check out the manual for the Free Dipole Kit in the Support/Manuals section of our website (click Here for the manuals page) ."

So I will have two HF antennae to run thur the tuner. I have a home brew multi frequency antenna I bought from a club member LVRAC. Looking forward to passing the general test by the time I have the radio set up.

Stay tuned, I will be asking something stupid when I learn enough to ask stupid questions.

73s
KE7WNX
Gene

With the wire tripled, wouldn't that be simular to a Cobra antenna???BillN8VWI
In a message dated 12/29/2008 3:54:39 PM Eastern Standard Time, callum@... writes:

Lee,

If you're feeding it with ladder line via a tuner then the only reason to doubling or tripling the wire will be to strengthen it. Forget it - save the rest for another day and keep it on the reel. Regarding bandwidth, since you have a tuner - it won't matter.

Your comment doesn't mention how long the ladder line is so I can't comment about the balun too much, however I would recommend one. You will have some fiddling with impedances, but I'm sure you are already aware of this!

Cheers,

Callum McCormick

Subject: [ham-antennas] new 160m dipole project

The plan is for a 160m dipole 260 feet long up in the air at the 80 foot mark.

I'm going to feed it with 600 ohm true ladder line the height of the 80 feet. Then use a air choke made of 9913 coax wrapped around 6" PVC pipe to be able to run the coax into a Ameritron ATR-15.
Going to use the wire mostly on 160/75 and one of the questions is should I use a balun for this project?

I the balun I am thinking is a 600/50 4KW military air cooled that I would put at the bottom of the 600 ohm ladder line feed which is 80 feet below the feed point.

I live on a rocky hill side and will point this NE/NW from central Alabama.

Thoughts would be appreciated. I have 1000 feet of #12 copper stranded and one thought would be doubling or even tripling the wire for more band width.

Ideas?

Lee

Cobra antenna, Bill? Is that a brand name or a 'fan' version of a dipole?
I have a 75m dipole that is made from #6. I use it to hold up the trees when the wind blows! haha

Yep, sure would...I have one of these and I like it. The three wires next to each other does bring some expanded bandwidth, but the professionally made one is resonant at about 2Mhz, with little bandwidth, meaning I can't get it to tune below 1.9Mhz.

I haven't used mine either yet, but from what I read, you have to have the interface cable between the tuner and radio. Then you just use the tune button on the radio. I might be wrong, probably am...Bill N8VWI

RR!! I think that it was surplus but cant wait to get it started up.
The company still makes them but outrageously expensive.

Do you think at 80 feet it would be worth going full wave out to
500 feet? Or would that be too low to make a difference?

From: Dan Schaaf
Topic: 7503 Message: 7522

My FT-920 doesn't have a tune button that will auto tune the tuner, so I have to press the tune button on the tuner itself.

Best Regards
Dan Schaaf

I haven't used mine either yet, but from what I read, you have to have the interface cable between the tuner and radio. Then you just use the tune button on the radio. I might be wrong, probably am...Bill N8VWI

From: Chris
Topic: 7500 Message: 7524

As much wire, as high as you can get it is never a bad thing. Man, I wish I had one 80' support, let alone enough for a loop.

Feed that thing with open wire line and you'll be surprised at how well it works.

7525. A 43 ft question??

Yahoo group: ham-antennas (2008)
Date: 2008-12-30 02:37:01 UTC
From: greathounder
Topic: 7525 Message: 7525

The directions on the 43ft antenna says it can be built 2 ways. One being heavely overlaped and using the 9ft whip for the top element. The other way is to use less over lap and use the 1 inch tube for the top element. Is there any advantage to having a thicker top, instead of the whip. They say the whip is less noticeable. In this neighborhood, who cares. Thanks Bill N8VWI

That's really not side beside. Those are daisy-changed to keep it from being long.
I was talking about 3 equal runs like a cage antenna.

Yep, sure would...I have one of these and I like it. The three wires next
to each other does bring some expanded bandwidth, but the professionally
made one is resonant at about 2Mhz, with little bandwidth, meaning I can't
get it to tune below 1.9Mhz.

That's true. Even if I don't talk any better extra wire for receiving will make a difference.
Got enough for a full WL 160, just thinking now about making a loop.

mmmm...????

I do NOT have any other cable attached to mine. I just feed in about 20
- 30 watts. It looks automatically to see if the frequency was used
before and uses the stored settings. If that frequency has not been used
before, it seeks out a match and then stores the info. It really is a
breeze to use and works quite well. You CAN add a cable from the
transceiver so you can use semi-automatic. Since mine is remotely
mounted, that wouldn't work for me, so I choose to use fully auto.

Have a Happy New Year.

7530. Re: [ham-antennas] Connecting the MFJ-998 tuner to the antenna feed point

Yahoo group: ham-antennas (2008)
Date: 2008-12-30 03:30:23 UTC
From: Steve Friis
Topic: 7503 Message: 7530

A good place to start is ALWAYS see what the manual says. Every brand of the same type of equipment operates in it's own way. What works for one brand may not work for another. Same for the transceiver. The manufacturers want you to enjoy your ham radio experience to the fullest. Sometimes just reading their manual can reveal a jewel and once you practice what they preach, you will find their equipment performs even better than you expect.

Hope to C U on the air. I do digi modes mostly.

Have a Happy New Year.

Steve/WM5Z

Sent: Monday, December 29, 2008 8:37 PM
To: ham-antennas@yahoogroups.com
Subject: [ham-antennas] A 43 ft question??

The directions on the 43ft antenna says it can be built 2 ways. One being heavely overlaped and using the 9ft whip for the top element. The other way is to use less over lap and use the 1 inch tube for the top element. Is there any advantage to having a thicker top, instead of the whip. They say the whip is less noticeable. In this neighborhood, who cares. Thanks Bill N8VWI

From: Jerry Stern
Topic: 7525 Message: 7532

I am not sure that is a true statement since by definition the 43' vertical is non-resonant on almost all the HF ham bands so how would the thickness of the last few feet affect the resonant badnwidth since you need a tuner across the entire band for each band?

Yahoo group: ham-antennas (2008)
Date: 2008-12-30 05:00:54 UTC
From: Jerry Stern
Topic: 7525 Message: 7534

I have played with my DX Engineering 43' fast taper vertical quite a bit. I don;t think I can improve the radial system as I have more than sixty 40-72 feet long radials (mostly >70feet long). I have tried shortening the vertical from 43' down to 27' feet in steps that would be odd-multiples.... I have tried coax feedline lengths ranging from 10 feet (With an MFJ antenna analyzer) out to 50 feet (in 10' increments) and then from 50 feet to 150 feet coax feedline in 25' increments (my shack is only about 65-70ft from the antenna). Bottom line line I cannot find a SWR lower than 2.5 on ANY HF band anywhere and most are SWR=3-5. 15m, 17m and 20m come the closest but could not operate without a tuner. What I have found quite odd is that for those bands where SWR without a tuner is below 2.5 that the autotuner has the most difficulty especially in the low end of the 15m and 10m bands. Have not gotten a good explanation except to play with more feedline coax length to find the best spot where there is the lowest voltage standing wave at both the tuner and at the antenna feedpoints. I have to say this has been a good exercise forcing me to read much more on transmission feedline impedance and I still feel like I am just scratching at the surface of all the technical details hihi. What is frustrating with even the best vertical system is that it will never come close in performace to a tower + directional beam. I was listening to a guy no more than 20 miles from me here in CT this afternoon making multiple easy contacts on 17m to ZL and VK with only 100w and I could not even hear those stations above the band noise (and 17m was fairly quiet then compared to 20m or 40m). So we have to do the best we can... I don't think the problem with working DX from Verticals is the TX side (especially with an amp) but rather the RX side so I will experiment in early Spring hanging wire for a better receiving antenna such as a short beverage or horizontal loop.

what happens if you change the antenna? will it use the stored info
instead of recalculating the setting?

7537. Re: [ham-antennas] new 160m dipole project

Yahoo group: ham-antennas (2008)
Date: 2008-12-30 13:34:57 UTC
From: Siegfried Jackstien
Topic: 7500 Message: 7537

you will never have 699 ohms after your ladderline so the balun will have to handle a lot of reactance
swr after the balun will be high and so you will have high loss on your coax

Subject: Re: [ham-antennas] new 160m dipole project

Hey Callum,
Long time my friend. Hope all is good in sister B'ham.

This is the balun http://cgi.ebay.com/ws/eBayISAPI.dll?ViewItem&item=110314062973&ssPageName=ADME:X:RTQ:US:1123<http://cgi.ebay.com/ws/eBayISAPI.dll?ViewItem&item=110314062973&ssPageName=ADME:X:RTQ:US:1123>
I have one like it. Thing cost like 3000.00 from maker.

Anyway, the ladder will be about 70 - 80 feet long. Up a tree to the main pulley. The balun will be mounted on the side of the house and a coax running inside thru a air choke.

What ya think?

Lee,

If you're feeding it with ladder line via a tuner then the only reason to doubling or tripling the wire will be to strengthen it. Forget it - save the rest for another day and keep it on the reel. Regarding bandwidth, since you have a tuner - it won't matter.

Your comment doesn't mention how long the ladder line is so I can't comment about the balun too much, however I would recommend one. You will have some fiddling with impedances, but I'm sure you are already aware of this!

Cheers,

Callum McCormick

Subject: [ham-antennas] new 160m dipole project

The plan is for a 160m dipole 260 feet long up in the air at the 80
foot mark.

I'm going to feed it with 600 ohm true ladder line the height of the
80 feet. Then use a air choke made of 9913 coax wrapped around 6" PVC
pipe to be able to run the coax into a Ameritron ATR-15.
Going to use the wire mostly on 160/75 and one of the questions is
should I use a balun for this project?

I the balun I am thinking is a 600/50 4KW military air cooled that I
would put at the bottom of the 600 ohm ladder line feed which is 80
feet below the feed point.

I live on a rocky hill side and will point this NE/NW from central
Alabama.

Thoughts would be appreciated. I have 1000 feet of #12 copper
stranded and one thought would be doubling or even tripling the wire
for more band width.

Ideas?

Topic: 7500 Message: 7538

if you have the room try a fullwave loop
i have it here about 40-50feet above ground and it works SUPERB ....
i have to switch between 2 different lenght of feedingline but with 2 bananaplugs it is done in a second
....
i have a quarterwave lenght of feedingline for 80 from feedingpoint to the shack and another 20m feedingline that is under the roof of the house in a circle .... all 3 ends are in my shack
so switching in the additional lenght is easy ...
cause the loop is not very high above ground the impedance is quite low at the feeding point
with the ladderline i transform it to about 400-500 ohms ....
in my tuner i have a homemade balun 1:9 to bring the ipedance down to 50 ohms
on many bands i don´t use the tuner (bridged) on the other bands the tuner in the trx can tune easy the mismatch
or you can use the pi-filter in the pa if you have one ....
see file "loop.xls" in the file area
it is an excelsheet what i made for my notes
so maybe that is a solution for you

RR!! I think that it was surplus but cant wait to get it started up.
The company still makes them but outrageously expensive.

Do you think at 80 feet it would be worth going full wave out to
500 feet? Or would that be too low to make a difference?

That's true. Even if I don't talk any better extra wire for receiving will make a difference.
Got enough for a full WL 160, just thinking now about making a loop.

As much wire, as high as you can get it is never a bad thing. Man, I wish I had one 80' support, let alone enough for a loop.

Feed that thing with open wire line and you'll be surprised at how well it works.

Subject: Re: [ham-antennas] Connecting the MFJ-998 tuner to the antenna feed point

A good place to start is ALWAYS see what the manual says. Every brand of
the same type of equipment operates in it's own way. What works for one
brand may not work for another. Same for the transceiver. The
manufacturers want you to enjoy your ham radio experience to the
fullest. Sometimes just reading their manual can reveal a jewel and once
you practice what they preach, you will find their equipment performs
even better than you expect.

Hope to C U on the air. I do digi modes mostly.

Have a Happy New Year.

Steve/WM5Z

From: Siegfried Jackstien
Topic: 7525 Message: 7541

put a capacitor in series and you have a quarterwave (extendet) for 40
put a coil in series and you have a 5/8 for 20
should work well
there is also a dualband network possible to work on both bands without switching

Subject: RE: [ham-antennas] A 43 ft question??

I am not sure that is a true statement since by definition the 43' vertical
is non-resonant on almost all the HF ham bands so how would the thickness of
the last few feet affect the resonant badnwidth since you need a tuner
across the entire band for each band?

Subject: [ham-antennas] A 43 ft question??

The directions on the 43ft antenna says it can be built 2 ways. One being heavely overlaped and using the 9ft whip for the top element. The other way is to use less over lap and use the 1 inch tube for the top element. Is there any advantage to having a thicker top, instead of the whip. They say the whip is less noticeable. In this neighborhood, who cares. Thanks Bill N8VWI

7542. Re: [ham-antennas] Connecting the MFJ-998 tuner to the antenna feed point

Yahoo group: ham-antennas (2008)
Date: 2008-12-30 14:24:59 UTC
From: Steve Friis
Topic: 7503 Message: 7542

Good question. But, since mine is hooked up to only one antenna, no way
to tell. It is on my multi-band Fan antenna covering 160-30 meters.

Have a Happy New Year.

Steve/WM5Z

7543. Re: A 43 ft question??

Yahoo group: ham-antennas (2008)
Date: 2008-12-30 14:54:23 UTC
From: billncolo36
Topic: 7525 Message: 7543

I believe that the statement is true.
First, we usually try to "operate" antennas near resonance, even if it is non-resonant by itself (that is in part what tuners are for).
Second, the bandwidth of an anntenna around resonance is determined by it's loaded Q. The higher the loaded Q, the more efficient the antenna is, but the bandwidth will be less. The Q will increase as the losses decrease. The losses will decrease for a vertical will decrease as the diameter of the radiator element is increased. The most reduction in loss occurs when the base diameter is increased, with almost no improvement from increasing the diameter at the top.
So, I think the answer to the original question is that there will probably be little/no measurable difference in loss resulting from the use a small diameter whip at the top. The bandwidth may be reduced slightly.

7544. Re: [ham-antennas] A 43 ft question??

Yahoo group: ham-antennas (2008)
Date: 2008-12-30 15:11:43 UTC
From: Dan Schaaf
Topic: 7525 Message: 7544

Here is the question:

1) You can spend $400 for the 43 ft antenna and additional money for a remote tuner

2) You can buy the new Cushcraft MAV160 for $250 which is linear loaded and then put capacitors at the base for 80 and 40 meters. Then use an MFJ remote switch to switch in/out the capacitors

Which is the best solution?

The MAV160 is resonant on 160. This is my dilemma for a future purchase. And the MAV160 is shorter in length. In addition, a tuner in the shack can make fine tune compensation in addition to the capacitors at the base of the MAV160.

Opinions?

Best Regards
Dan Schaaf

put a capacitor in series and you have a quarterwave (extendet) for 40
put a coil in series and you have a 5/8 for 20
should work well
there is also a dualband network possible to work on both bands without switching

I am not sure that is a true statement since by definition the 43' vertical is non-resonant on almost all the HF ham bands so how would the thickness of the last few feet affect the resonant badnwidth since you need a tuner across the entire band for each band?

I would like to challenge (only for the sake of learning) the statement in the context we were discussing. Perhaps going from small gauge solid copper wire to larger gauge solid wire you would have less loss so higher Q but please show me a reference that will explain how a 1" diameter aluminum pole will have more loss than a 1.5" or even 2" diameter pole? There has to be a point beyond which the diameter makes essentially no difference in the calculations

I think it is at the point where the diameter is equal to the radiator length. But, keep in mind that approaching those ratios have their own problems. For one, calculating the length by formula is really interesting. Another would be feeding it. On paper it looks easy, in actuality, it doesn't work.

Have a Happy New Year.

Topic: 7500 Message: 7548

Kevin,

At 80 feet, this will work fabulously. Have you seen my articles on large loop equilateral triangles? If you can get this into a triangle, all the better. My two-wavelength loop is at about 80 ☐ 85 feet too. I can hold a pile-up into Washington on 10 watts!

Yes, use the balun on the ground with ladder line up to the loop. You will get some strange impedances and you may have to lengthen / shorten the ladderline. If James is reading this, he may be able to add some further info.

Cheers,

Callum McCormick
http://www.m0mcx.co.uk/

If I build it, you might hear me.

RR!! I think that it was surplus but cant wait to get it started up. The company still makes them but outrageously expensive.

Do you think at 80 feet it would be worth going full wave out to 500 feet? Or would that be too low to make a difference?

Lee

I have one like it. Thing cost like 3000.00 from maker.

I have included a diagram in the 'Files' section. Maybe that will help
some?

My reasoning behind the design is that the copper antenna inside of the
PVC/Electrical conduit is that I hoped it would behave more as coax
cable would as it is similar in physical desgn (although much larger)
to coax (the metal surrounding a non-conducting material surrounding
the signal-path conductor). At least that was the logic behind the
idea.

Jerry, Good question, however, the answer is very dependent on the type of antenna, soil conditions, etc. One of Cebik's articles ("Antenna Bandwidth") models a dipole for various element diameters. You can download the article from his website, but the bottom-line is that dipole bandwidth nearly doubles going from #28 AWG to 1 inch diameter. On 3.5 MHz, this means that 170 KHz goes to 300 KHz. Verticals are more complicated due to the effect of ground losses, but the trend is the same. Shortened verticals are especially sensitive to element diameter, and that is when wire cages (frequently 6-12 inches in diameter) and capacitive "hats" are frequently used. For me, I usually spend most of my time dealing with take-off angles, which can make 10's of dB of difference and ground losses. I have noticed that the 43 ft verticals do a good job on 20M (where the models predict good performance), but I suspect some of the owners of these antennas are dissappointed with them on some of the other bands.

The copper pipe inside the EMT will be like a tuning stub or a capacitor. It will probably work, but I'm not sure what effect it will have on tuning. You might look into feeding it at the base and putting the radials on the ground level.

So if I understand correctly, using the 1" tube for the top, might get me a little more band width? And with the insert in the 1" section, I might be able to have a hat on the top. I've got to find my old antenna book. Do you have any suggestion of how long the rods would have to be, coming out to the sides? Thanks for all the good information...Bill...N8VWI

I'm not quite sure I understand your question. What exactly is it you are trying to do? The loss associated with the element diameter is largely an "IR" loss. However, since the current in a vertical is maximum at the base, and dimenishes (not linearly) to zero at the top, the benefit from reducing R also dimenishes to zero as you move the point of reduction from the base to the top.

Granted nothing is perfect but you say never 600 ohms after.
It is 600 ohm open wire ladder, not 450 ohm.

The coax will be short, 50 feet including 20 feet for a air choke.
Then tuned with a 'T' network tuner.

Also this antenna will be most likely a full wavelength so none of
the issues with a too short antenna. Such as a G5RV.

Lee,

If you're feeding it with ladder line via a tuner then the only reason to doubling or tripling the wire will be to strengthen it. Forget it - save the rest for another day and keep it on the reel. Regarding bandwidth, since you have a tuner - it won't matter.

Your comment doesn't mention how long the ladder line is so I can't comment about the balun too much, however I would recommend one. You will have some fiddling with impedances, but I'm sure you are already aware of this!

Cheers,

Callum McCormick

Subject: [ham-antennas] new 160m dipole project

The plan is for a 160m dipole 260 feet long up in the air at the 80 foot mark.

I'm going to feed it with 600 ohm true ladder line the height of the 80 feet. Then use a air choke made of 9913 coax wrapped around 6" PVC pipe to be able to run the coax into a Ameritron ATR-15.
Going to use the wire mostly on 160/75 and one of the questions is should I use a balun for this project?

I the balun I am thinking is a 600/50 4KW military air cooled that I would put at the bottom of the 600 ohm ladder line feed which is 80 feet below the feed point.

I live on a rocky hill side and will point this NE/NW from central Alabama.

Thoughts would be appreciated. I have 1000 feet of #12 copper stranded and one thought would be doubling or even tripling the wire for more band width.

Ideas?

7556. 33Ft / 43Ft Antenna

Yahoo group: ham-antennas (2008)
Date: 2008-12-31 02:24:05 UTC
From: Richard Schmuke
Topic: 7556 Message: 7556

After following the thread on the 43 Ft antenna I remember reading about a
40/20 meter vertical. I looked up the article and it was in Sept 2005 QST ,
it is also on Dan Richardson□s web site, K6MHE. He and Wes Hayward W7ZOI
came up with a way to work two bands on one antenna with no switching relays
or store bought tuner.

Rich , KDØZZ

These are the humble ramblings of an old phart and in no way should they
influence the actions of any intelligent and sane person

if you take a quarterwave lenght of ladderline for the lowest band the line transforms the low impedance of the dipole to a few hundred ohms ... balun is in good working condition on 80 (for a 160m dipole) feedingline is halfwave so no transforming ....
the high impedance of the fullwave dipole is present at the balun and it will work also
if you take a proper lenght of the ladderline you will have low losses on the coax after the balun
see my excelfile here in the filearea ....
it is from my fullwaveloop 168m fed with 2 different lenght of ladderline
if you do this like i did it will work fine
if you have a random lenght of ladderline (not quarterwave) the swr will be high on the output of the balun and it will have to handle a lot of reactace
after the balun the swr on the coax will be high so losses are high
i spent 4 days with cut and try cut and try etc....
but now i have a real multibandantenna with low losses
i work only barefoot 100w so i wanted an antenna where i need no tuner or where i have only a slight
mismatch .... i wanted to have as much power as i can get out of the system
okay.... if feedingline is short the losses will be not to high but you can perform better if you don´t need a tuner.....
best wishes to 2009

I wonder, should I use the analyzer before the balun or after? If after no issue, just plug it in. Before I will have to make a ladder to coax adapter.

Thoughts?
